As the work of excavating progressed and the gravel was exposed, there was found a clearly defined depression diagonally across the pit, as if at some time the brook had flowed that way; for logs and trunks of trees were found together with a quantity of brush. Through this depressiou the gravel was very thin, and in three places the quicksand was entirely exposed—the first, a space 10 by 15 feet; the second, a space 4 by 12 feet; the third, a space 3 by 15 feet.

Hardly had the whole of the loam been removed when a rain came, followed by a heavy freshet, overflowing the meadow and deluging the pit. When the water had subsided it was pumped out in 8 hours with a 4-inch centrifugal pump and a 7½ horse-power motor, though the water was ten feet deep in some places. The freshet convinced the company more than ever that in erecting a holder it would be advisable to make the top of the foundation above high-water mark, which in this case would mean a fill in some spots of 12 feet, with an average of 8 feet, and the steel tank would be 2.5 feet above the level of the meadow.

At this point a difficult problem was confronted. Meriden topographically is on high hills and in a sandy valley; good gravel is a very scarce article. Four miles away, on the line of the railroad, is a large, poor gravel bank, and two miles in another direction is a small, good bank; but with all the teams that could be procured it was not possible to haul the material as fast as it was needed; and it was expensive—one dollar per yard—delivered. It was evident that other and good material must be obtained in large quantities. On the line of the railroad three miles away is a large trap-rock quarry. Refuse in the shape of iron-stone, soft rock and some dirt is accumulated in large quantities. It was believed this stone would mix well with the material which was on hand and could be purchased after it had been passed through the crusher to a 1½-inch size, at 60 cents per yard delivered, and in quantities up to 150 yards per day. About 50 yards of gravel and 50 yards of clean, sharp sand could also be procured each day, and as much ashes from the works as there were teams to put on it.

The question of piling was considered, and by some might seem the only wise plan under the circumstances, but after consulting the leading local builder who had worked on this quicksand for thirty years and had erected some very heavy factory buildings on it, it was thought best to put in a combination filling of the above-named materials.

The quicksand is found hard packed and not easily dug, unless water is allowed to mix freely with it. Although the excavation was in places much below the level of the brook, little water was encountered, and quite as much came from the land as from the brook side. By keeping the bare spots well drained the men could work on the quicksand with a degree of ease without sinking in very deep; the less it was disturbed, however, the better off they were. Over these bare spots it was decided to lay plank close together lengthways of the holes, and upon these 8 by 10-inch timbers, 8 inches apart, crossways of the holes. The filling between the timbers was of pieces of bricks and old retorts broken up fine, that being the best material at hand just then. One of the bare spots being narrow and long, the surface was covered with large flat stones, the smaller spaces being filled in with fire-bricks and coarse ashes.

While working at this low level a pump was run night and day; also from these quicksand spots a 4-inch tile drain was laid to a central point to facilitate drainage and keep the mass from becoming spongy while the tamping was going on and each course of filling was laid.

Until the whole surface approached a level no roller could be used, but everything put in was thoroughly rammed and sprinkled. The layers were about 3 inches thick over the whole surface. When the valleys were evened up a two-horse 4,000 lbs. roller was put on, and as the thickness became greater this roller was increased in weight to 6,500 lbs., requiring four horses. When the level of filling had been raised above the natural water level the pumping was dispensed with over night, allowing the foundation to be saturated, but it was pumped out again in the morning.

Near the centre of the foundation a loose brick well was built up, into which the water ran as the foundation was successively wetted, and from which it was pumped to the brook. There were some high knolls of gravel not over 3 feet under the surface. It was thought at first that the 5-feet concrete side wall foundation might rest on these, but further consideration convinced the company that this was not advisable, as part of the foundation would rest on natural gravel, while most of it would be on filled ground, so the whole level was raised 1 foot to allow of the same kind of cushion underneath the whole structure before the 5-feet circle was started.

* From a paper by Mr. C. A. Learned, read before the New England Association of Gas Engineers.

The layers spread each day over a diameter of 125 feet were about as follows:—125 yards of quarry refuse, 40 yards of good gravel, 50 yards of works' ashes. Towards the end of the work the ashes were exhausted. Near by was a bank of 500 yards of sand, and from this was taken what was needed to make the top dressing under the concrete, spreading on the stone, washing it in and carefully rolling. Toward the end the roller worked night and day.

Near the edge where the wall of concrete was laid, there was a space that could not be rolled, but had to be filled and tamped to a depth of 4 feet. In order to make sure that this portion was as solid as the centre, a round tapering bar 5 feet long was driven into the cement, 2½ of sand and 5 of stone. The size of stone was 1¼ inch and smaller. A great circle of concrete 4 feet wide and 1 foot thick was laid 5 feet below the finished top. On this circle was laid a ring 3 feet wide at the bottom, tapering to 2 feet 9 inches wide at the top, and 3 feet high; resting on the ring was laid, over the whole diameter of 118 feet, a layer 1 foot thick, trued to prelect level and plastered smooth. This work was accomplished in eighteen days, and in a most satisfactory manner, a local engineer taking the job at 4.90 dols. per cubic yard laid. As soon as the foundation was ready the iron men were on the ground, and the holder was erected complete in a week less than the specified time of four months.

main foundation several times. Seventy blows on the average were required to drive it 4·5 feet, and the outside ring was tamped until it equalled the above test.

The amount of material removed approximated 2,900 yards. The work of excavating and filling ready to begin concreting took twenty-two days, and six days more were required to fill in around the great circle after the concrete wall was 4 feet high. This, however, did not delay the concreters in their work. The filling was as per the following amounts:—Quarry stone refuse, 1,780 yards; gravel, 680 yards; sand, 310 yards; ashes, 1,100 yards; total, 3,870 yards.

On this foundation was laid 630 yards of Portland cement concrete, in the following proportions:—1 of

In order to prevent the action of the brook eating away the bank near the holder, a stone wall 7 feet high was built to the level of the holder foundation and 400 feet long, protecting also a new purifier building near the brook. City water was used to fill the tank, as the brook water contained acids. It took three and a half days to fill the tank, which holds a little over 2,000,000 gallons. Before the water was put in careful levels were taken on eight points of the foundations. After filling levels were again taken, and there was not the slightest settlement.

The Montreal Silicate Brick Company, has been incorporated, with a capital of $100,000.

BY THE WAY.

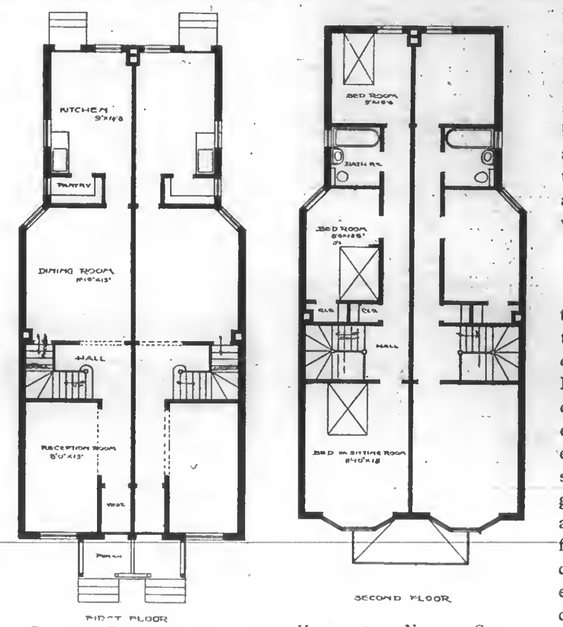
The present popularity of all kinds of athletic sports calls for the erection of tiers of seats for the accommodation of the enormous crowds of on-lookers. That great case should be exercised in their construction is evidenced by the accident which took place in Glasgow recently, when 21 persons were killed and 250 injured by the collapse of the "Grand Stand" during a foot-ball match.

× × ×

The Chinese have been demolishing walls outside the Summer Palace at Pekin, and selling the bricks to the various Legations where building is going on, the Ministers being in ignorance of where they were obtained from. But Nemesis sometimes overtakes even the "wily Chinee," says the British Clayworker, and investigation has led to the arrest and punishment of six of the offenders. The Legations ought now to be invulnerable, since sacred bricks have been employed in the'r fortification. When we come to reflect on the matter, however, the Ministers must be an extremely ignorant body not to know a new brick from an old one—perhaps they winked at Master John whilst the transference to their own abodes was taking place, bricks being particularly scarce in Pekin just now.

× × ×

A verdict for £150 was recently given by an English jury against the proprietor of Her Majesty's Theatre in London in favor of a person named Davies who was injured by slipping from a 6 inch step while hurriedly making his exit from the building. The Builder points out that this should serve as a warning to architects not to plant a door on the top of a 6 inch step so that the fact of the existence of a step is only visible from one side of the door.



PLANS OF PAIR OF SEMI-DETACHED HOUSES ON A NARROW SITE, TORONTO.—F. F. SAUNDERS, ARCHITECT.

× × ×

Some twenty five years ago a friend of Mr. Aston Webb's wrote a little ditty which described the progress of a young man who started as office boy with a builder and passed through the various ranks until he became an architect. When he reached the position of clerk of works the ditty described him thus:—

When builder's work he found it tame,
So clerk of works he next became;
The work was less, the wages more,
And he liked to boss the contractor.
He wore a two-foot rule and suit of grey,
And now he is a F. R. I. B. A.

The Monetary Times contributes the following to the long catalogue of unreasonable demands of the labor unions:—"We know of a case in an Ontario city last autumn where a block of brick buildings was in process of erection, and some bricks of peculiar wedge-shaped form had been ordered from a brick works to be ground to pattern by machinery. The architect was on the structure one day, and a delegate from a labor union came to inform him that these tapering bricks must be ground down by hand—the Union said so. "But," said the architect, "there are not enough bricklayers in the city to contruct before the snow comes the buildings already under contract; why do you want to delay by putting hand-work on these bricks?" There was no answer but the irrational one, that it was the Union's ultimatum. The architect, who is not a patient man, ordered the walking delegate off the works, using a Shakespearean phrase, and declining to be bullied. But, next day, not a man was at work on the block, bricklayer, carpenter, or plumber. The architect, consistent even in his wrath, went to look for non-union men to complete the walls and other work, when the owner of the building, himself a large employer of labor, interposed and accepted the Union's terms rather than have a strike in his own works.

× × ×

Much of the architectural terra-cotta of the day in the opinion of a writer in the British Clayworker, is decidedly over-finished. Apart from slovenly and careless work says the writer, two grades only of "finish" are possible — right finish, or the full rendering of the intended expression; high finish, or the rendering of vivid expression. These, and indeed all the best effects, are oftener got by rough than fine handling. Excellence in architectural terra-cotta, particularly in ornament, is not attained so much by the cutting of the form, it is rather in the ultimate effect of the mass. The correct finish is about that of a modelled piece, made in the same material employed in bulk on the building, after leaving the architectural modeller's hands, the presser or mould-maker's shop. After the mould is made, the presser or finisher, by the excessive use of sponge, leather, knife and busk, destroys all the life and spirit formerly existing in the work, to say nothing of the false surfaces, which readily flake, on the faces of the wares, worked up by excessive finishing. Look at a piece of direct work; work straight from the architectural modeller's hands, without the intervention of mould, presser, or finisher. Note this in a building, side by side with pressed-up wares; if the modeller is worth his salt there will be life and spirit in the work, attributes too often lacking in the doubtless more highly-finished samples of the moulder's art!

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Conetructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Office: IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.

Bell Telephone 2299.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

It has been decided to hold the annual convention of the National Plumbers' Association of Canada at Halifax, Nova Scotia, on August 13th and 14th.

Mr. Charles E. Langley, of the firm of Langley & Langley, architects, Toronte, is receiving the congratulations of numerous friends on his marriage to Anna M., second daughter of James White, of Woodstock, Ont. The ceremony took place at Woodstock, on the 12th inst.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

Toronto City Commissioner.

The City Commissioner's office remains in statu quo for the present but must have a change, soon and the opportunity ought then to be taken to make its organization perfect. An offer has been made by the architects of Toronto to appoint an advisory committee to work with the committee of the City Council charged with the reorganization of this department. The offer was made when it was understood that reorganization was at the point of settlement. The matter was postponed but the offer remains and has been filed for reference. It only remains for some one to see that it is referred to. This is a good offer; one which will introduce into the reorganizing body the technical knowledge that is necessary; and help to make whatever appointment is made a serviceable appointment, settled upon its merits.

The Stability of Walls in Case of Fire.

THE death of five firemen in consequence of a falling wall, at the burning of the warehouse of P. McIntosh & Son, recently in Toronto, shows the need of a provision in the city building law to prevent the construction of walls which are too long for their height and thickness. Walls that depend for their stability upon the stay provided by the floor beams and trusses are a danger in fires. The wall of the old street car shed, which was occupied by Messrs. McIntosh & Son, should never have been built of so great a length without cross walls. The ruins show a wall 40 feet high, running for 145 paces, or about 425 feet without cross walls. The proper thickness for such a wall would be a little over 3 feet; the actual thickness is 18 inches stiffened by a buttress of 4-inch projection, at intervals varying from 16 to 32 feet. Buttress and all the wall is little more than half thick enough. Such a wall could be safely built only because stayed at intervals by joists and loaded with roof trusses; and, when all these stays are taken away at once, with a shock, in the midst of the violent movements of air in a fire, its downfall is certain. It is not possible to tell from the outside how a long wall is braced; and, unless the chief of the fire brigade is to be familiar with the plans of all buildings, he can never be sure that a long wall is thick enough to stay up after the floors fall in. The by-laws ought to have a provision which will assure him on this point, by making all walls thick enough to stand unsupported.

Are Architects a Commercial Necessity.

A notable instance in Montreal recently of a contract to design and deliver a building for a fixed price, which, in the case in question, appeared to relieve a situation of some difficulty, raises the question whether this would

not be the most direct way for building owners to proceed in all cases; whether it would not be better to make the contractor the responsible person, not the architect. Both functions are necessary; but, if the contractor cannot design himself, he can employ an architect. Would the owner be any the worse for this change of relation between the architect and contractor? Would he not be the better by the disappearance of the uncertainty that now sometimes attends the ultimate price of a building? Why should not buildings be built to order, just as clothes are made to order, for a fixed price? A reputable tailor does not fail us in respect of either design, material or workmanship. It is understood that these qualities are to be assured to us at a fixed price, and the tailor's reputation depends upon the faithful fulfilment of the understanding. Why then cannot a reputable builder be trusted to provide us a building to order upon the same terms? A builder's reputation depends upon his work as much as a tailor's! That is true; but does he depend so much upon his reputation? A tailor's unit of production is small, and its period of duration is short however well it is made. A tailor has to make many many coats before he can make a fortune. Patient continuance in well doing is his only hope for this world as well as for the next. But the contractor!—One good contract scientifically scamped will easily yield a fortune, and the result need not show too soon. What is reputation to a man who can make a fortune before he is found out? Wealth—I speak as a man—is the best reputation. The case of the tailor is not an illustration in point. It is but an illustration of the danger of reasoning from analogy.

The architect is then a commercial necessity, to fix and keep up a good standard of work which, were he not the responsible arbiter, would speedily dwindle. Nor would the architect himself, in these conditions, have the stimulus an artist needs.

The Toronto Plumbers' Strike.

The plumbers of Toronto entered into a wage agreement in 1900, which, according to the conditions of the agreement, is "to stay in force until the first day of January, 1904. And should either party to this agreement wish to change, add to or amend the above, they shall give a least three months' notice in writing prior to the termination of this agreement." The men, after a year of the agreement, have struck for an increase of wages after giving three months notice, and say that this is their interpretation of the above clause. The implication that to express a desire for the termination of an agreement upon a certain date is the same thing as procuring its termination on that date is—considering that the consent of the other party to the agreement is necessary for such termination— a piece of presumption which may be warranted by previous occurrences of the kind; but the only sort of previous occurrence of any kind, that will avail to give this interpretation weight in law, is a judge's decision that the date of the termination of an agreement, which has been fixed by the consent of both parties to the agreement, can be altered at the dictation of one; and the most patient research is not likely to result in the discovery of such a decision in the records of English law. The men have no case, and must know it, because the organizer of their own union has visited Toronto to tell them so. Their own common sense must tell them that the employers cannot possibly make a second agreement with them, in good faith, upon the basis of this broken agreement. The employers will feel justified, and will be considered by other people to be justified, in breaking the new agreement whenever they find it expedient to do so. In other words, the plumbers' action in this matter is an injury to the steady development of the condition of labor, and the best thing that their own party can do is to make common cause with the employers against them.

Adding to Another Architect's Work.

In France, among architects of the inner circle, not only is a designer's drawing his private property but even, so long as he is alive, his executed conception. If an owner wishes to add to his building with the help of a new architect he must expect a new design, for the new architect would think it an infringement of professional etiquette to repeat an idea developed in his predecessor's work. As an aid to establishing the permanent relation between architect and client that the profession upholds as the ideal, this practice is a good one. An owner will not be so likely to change his architect for trifling reasons. He will be at any rate most likely to put an addition into the hands of the original designer. But as to the question of a substitute architect evading the awkwardness of working with another man's design by diverging from it in the points which distinguish it, the fundamental value of this phase of etiquette is doubtful. Granted that the owner knows and accepts the consequence of a change of architects, and that his interest in the matter need not affect the question; as a matter only of etiquette—if all consideration is to be centred on the original architect, the proprietor of the design—would not his interest be best served by following out his ideas as much as possible in the new work? Variation is competition; and, if the original designer has any proprietary right in the executed design, it ought to be the right to demand its continuation. Etiquette comes in in the maintenance of good relations between the architects. The quarrel, if there is one, is not their quarrel. A superseding architect owes it to his own reputation as well as to the undefined interest which the original architect has in the design to communicate with the original architect, if they are neighbours, in the same town or association. If he does not feel at ease in his position enough to do this, and cannot explain his position, the presumption is that he is a deliberate supplanter; an offender against, not only the original architect of the building, but the whole profession. Of course these remarks do not apply to trifles but to buildings of a certain importance, such as that upon which these remarks are based, which is now being added to in Montreal.

The Campanile of St. Mark's.

As we go to press comes the news that "the detached bell tower of St. Mark's church of Venice which was founded in 888 has collapsed utterly". This can only mean a total fall in some manner and to those who are familiar with the importance of the campanile as a feature, not only in the piazza of St. Mark, but as an essential part of the group of buildings seen from the lagoon, this piece of news is of far more enduring importance than that of the resignation of Lord Salisbury and the reconstruction of the British Cabinet. The failure of the campanile must be in the foundations which are the ancient part. The shaft and belfry stage are comparatively modern. Some restoration of the foundation was undertaken less than twenty years ago and a piece of one of the piles that was cut was given to a Toronto architect by one of the engineers in charge of the construction. The pile was of oak and the piece taken from it, though showing the structure of wood and the appearance of oak, is almost as hard as stone. The failure of the foundation cannot be due to the failure of the piles themselves, but to some cause of which we await an explanation with the greater anxiety from consideration of the proximity of St. Mark's and the recollection that its orginal toundation was earlier than that of the campanile.

The Construction of Grand Stands

THE investigation into the cause of the collapse of the Grand Stand during a football match at Glasgow has brought to the surface valuable information with regard to what are the essentials in planning and construction of such structures necessary to insure the safety of the persons who may use them. The problem has become a difficult one in view of the enormous crowds for whom accommodation must be provided. The Grand Stand in Glasgow was an enormous structure, capable of containing 80,000 persons. Unlike the great amphitheatres of ancient times, it was constructed not of solid masonry but principally of wood, steel and concrete. Following are the quantities of material used in its construction: 1,500 lineal yards of fencing, 1,000 tons of concrete for the bedding of the iron girders, twenty-eight miles of pitch pine treads, twelve miles of girders, nine miles of columns, two miles seating, 700 hundred tons of steel, 15,000 square yards tufting, and two miles drain pipes. Between the tiers of seats was a net work of supporting timbers on which the victims of the accident fell and were "broken" in their descent to the ground 40 feet below. The stand appears to have been a substantial affair as such structures go, and the plans were submitted to and approved of by the district surveyor and board. The result has shown, however, that sufficient provision was not made for the tremendous strains imposed by the swaying to and fro within a concentrated area of such an immense assemblage of people. On this point Mr. Edwin O. Sacks, the well-known theatre architect of London, says: "In respect to the terrible accident to the staging at Glasgow, the only thing I should like to observe is that the effect of the moving or live load, such as a crowd of people swaying their bodies but slightly, is enormous, while the effect becomes terribly dangerous when the swaying of the body is accompanied by a shifting of feet. In watching a game in an arena the eyes of every individual in the crowd naturally follow an interesting feature of the game, which may at one time be to the left and at another time to the right of his seat or perch. With the movement of the eyes there is generally a slight movement of the head and upper part of the figure, and at exciting moments the whole body is frequently strained in one or the other direction, and often accompanied by a change of position in the feet. This is done rhythmically by thousands at a time, and the movement thus caused is accompanied by the gravest of risks." It may reasonably be expected that the Glasgow tragedy will lead to the exercise of more exact knowledge and greater care in the planning and building of structures of a similar character, not only in Great Britain but throughout the world.

NOTES OF A VISIT TO THE NEW BUILDING OF THE NEW YORK STOCK EXCHANGE.

Anyone looking at the plan of the New York Stock Exchange will see that it is a rectangle with lugs at diagonally opposite corners—N.W. and S.E. The rectangle runs from street to street in its long direction and the lugs are taken out of the lots to the North and South, which are otherwise completely built over.

The lugs are very useful for entrances, elevators, etc., so as to leave the main rectangle clear for the Stock Exchange; and it is this clear area that in considering either design or construction constitutes the building. Both in the foundation and in the upper flnors these annexes have no share in the great problems of the building, and while we are considering these problems we may dismiss these annexes and look upon the buildiog as for all practical purposes the great hall of the Stock Exchange which occupies the whole rectangle, 112 by 138 feet, inside measurement, and eighty feet high. The 138 feet run from street to street and the light comes from these ends, through the great portico on Broad Street, that we know from drawings, and a plain colonnade of equal dimensions on the New Street side. In addition to these windows there is a skylight in the ceiling. This is at the bottom of a light well for three or four storeys of administration rooms which, appearing as a blank attic above the Broad Street portico form internally and on the New Street side, well lighted offices. This then is the general scheme of the Stock Exchange; a chamber on the ground floor occupying the whole area; several tiers of offices above, which do not appear in the design; and sufficient basement.

It is the sufficiency of the basement that has required most from the engineer and was the principal object of interest in a visit to the works.

As we entered the building the water level was plainly visible, in a trench along the outside, standing at between 10 and 14 feet below the street level. When therefore we stepped on a wheelbarrow elevator and dropped through three storeys of steel beams, for a distance which we found was 42 feet below the ground line, it was evident that, while the building was classic architecture above the street, it must be something of the nature of naval architecture below. And this we found to be the case.

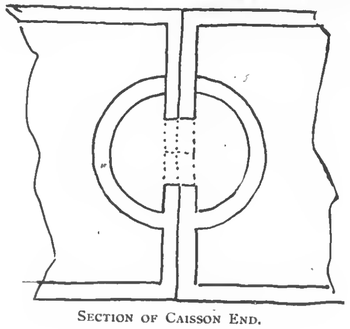
It has been customary of late in New York to carry the foundation down to the bed rock, either as a continuous wall or in the form of piers, excavating for this purpose, by means of pneumatic caissons, the quicksand that lies above the rock. But the excavation for the cellar has stopped short of the water level, which down town is not very far below the surface. At the site of the Stock Exchange the water level, as has been said, was about 15 feet down. A cellar this depth was not nearly sufficient for the elaborate mechanical ar-

STORE FRONT, KING STREET WEST, TORONTO.
SMITH & GEMMELL, ARCHITECTS.

rangements for heating, ventilation, the supply of power and other purposes which will occupy the basements of the Stock Exchange. It was therefore determined to excavate the whole mass of quicksand and gravel down to the bed rock, which Mr. Amory Coffin, Mr. Post's engineer, decided from borings would be found nearly level at about 50 feet down.

The case was therefore not the ordinary problem of sinking a wall to stand in the water. The wall might in this case be very easily sunk in parts, so as to be in effect continuous piers. Where there was water inside and water outside at the same level, an open joint between the portions of wall would be of no moment. But, when the space inside the walls was to be excavated for some 25 feet below the level of water standing outside, it became necessary to devise some means of locking the sections of wall together so as to make them water tight.

The ordinary pneumatic caisson was used 8½ feet wide (the thickness of the wall) and in 15 foot lengths. The working chamber had a domed steel roof, about 8 feet above the cutting edge, and the air shaft rose from the middle of this. The peculiarity of the caissons was that the ends which were square, the better to facilitate square and true sinking, were false ends. The true end was concave for the middle 4 feet, so that when two caissons were put together a cylindrical



Section of Caisson End.

space was left to be subsequently filled in with concrete. The square ends were planed and greased and sunk with great care so that the clearance was as little as possible—from ¼ to 2 inches. Then the middle planks (shown by dotted lines), which had been tapered for the purpose, were removed from the square ends, and the joint between the remaining portion of ends which projected into the cylindrical well, caulked and drawn tightly together by means of bolts. This caulked and bolted joint on the outer side of the wall will be always immersed in water and may be relied upon to be permanent and to keep out water as effectually as the caulked joint between the planks of a ship.

Having made the joint between the sections of the wall watertight the next thing was to attend to the close connections of the footing and the rock, so that this junction might be watertight also. To accomplish this the rock bottom inside the caisson was cleaned and washed and a footing of 6 inch concrete upon this was set under air pressure. Then the working chamber was filled with concrete and a thin grout of Portland cement run in and forced everywhere by air pressure until the pressure held for ten minutes at 20 pounds. In this way also the shrinkage in the wall above the working chamber was made good. Finally the cylinder of concrete connecting the caisson ends of the wall sections was thrown in and the air shaft filled up.

The result has been satisfactory. There is a certain amount of seepage, which is collected in a pit sunk below the cellar bottom and pumped up to the drain.

The deep cellar thus obtained has three storeys below the street level, and Mr. Coffin has made use of these floors as struts to brace his concrete wall against the heavy pressure from without. In order to do this effectually caissons for the 37 steel columns upon which the floor of the Stock Exchange and the three floors below are carried, were sunk down to the rock, and the columns were built in them, while the walls, which have been described above, were being sunk. Thus the walls and columns were both in place before the excavation was begun, and, as soon as the excavation got down to the level of a floor, the floor framing was inserted, and stayed the external walls in place of the stuff which had been removed. The central bays of the floor frame are well cross braced to form an immoveable abutment for the external bays to thrust against, and the ends of the external girders are fitted to a brace girdle of heavy I beams, set with the web horizontal.

The space thus procured under the ground floor is all wanted. The four floors are called respectively the basement, cellar and first and second sub-basements. In the sub-basements are the boilers and engines, the heating, cooling and ventilating plants. The cellar seemed to be chiefly valuable as a free place to run the innumerable wires and pneumatic tubes which are necessary for the elaborate contrivance for saving and expediting work in the Stock Exchange. There is also on this floor a large safe deposit vault, which was a problem by itself. The original vault was of stone. It was determined to leave this as it was, and the caisson sinking and excavation went on around and under it, leaving the vault and an enclosed passageway of approach undisturbed so that its business went on as usual all through the building operations. When it was finally decided to substitute for it a steel vault, the new vault was built alongside ; and the move from one vault to another made between Saturday afternoon and Monday morning, so that the vault was not out of working order for an hour.

The cellar and sub-basements set free the basement, or storey on a level with the street, for the telegraph offices, locker and toilet rooms and other supplementary needs of the Stock Exchange, so that the main floor and entrance may be kept free for members. The two or three hundred employees will have a basement entrance of their own and basement passages to their elevators, so that the employees and members need never meet in coming and going and, as far as planning can bring it about, the Stock Exchange will go about its business in a dignified manner.

The great room of the Stock Exchange is chiefly remarkable, in point of constructional detail showing in its unfinished state, for the trusses of 112 feet span to carry the four storeys of offices on each side of the light wall. The trusses are therefore on each side of the skylight in pairs, each 15 feet deep and 4 feet wide on the flange. Being 80 feet high they do not look excessive.

The entire walls were being covered with marble when we were there. The entire space behind the columns of the portico is to be filled with plate glass. For this purpose steel mullions are inserted behind the columns. The mullions are supported from above and, as there is a large surface of wind pressure to resist, they are made of 18 inch I beams.

When the marble and the glass and the ceiling finish are in place one will have to go far to find one single room so large and fine as this.

Smith & Gemmell, Architects.

RELATION OF THE ARCHITECT AND THE LANDSCAPE ARCHITECT.*

We have been considering the beginning and growth of landscape architecture. Let us now so far forget these facts, both historical and present, that we may conceive of the profession as having attained a recognized membership in the sisterhood of the arts. The reason for thus taxing your imagination is that I may discuss, in a general way, the probable or ideal relation of the architect and the landscape architect. It will be recalled that the last of the 17th century found the architect supreme over house and grounds, but that the beginning of the 18th century found the architect confined to the house, while the grounds fell to the independent charge of the landscape architect. On the one hand, the architect felt that his domain had been usurped by a people unsympathetic in their feelings and incapable in their lack of training to govern that field which he had been compelled to evacuate ; while on the other hand, the usurpers no doubt felt, at least to a degree, the justice of this reproach and were therefore stimulated the more to differentiate their value, first by ridiculing the traditional style of designing grounds, and second, by creating a taste for a new style that in every way diverged from the traditional. Hence, there was little success in harmonizing the two interests which had heretofore been one, for the simple reason that there were two heads for the two distinct departments, working not only independently but even antagonistically. The extent to which this spirit of antagonism still lingers between the architect and the landscape architect is somewhat uncertain. Opinions will vary according to experiences. It is certainly less than it was, but more than it ought to be. It is a question which though easily solved theoretically, must in practice be worked out by the sum of individual experiences. This question has been mooted from the very inception of landscape architecture, and as long as it remains unsettled the related work of the architect and the landscape architect will be inharmonious. There can be no doubt as to the true cause for the continual inhospitality of the architects, for as a class, they represent a thoroughly trained capacity for design, while the landscape architects, as a class, represent quite the reverse. In other words, it is the friction which must inevitably arise when scientific training is pitted against knowledge which is purely empirical. This difficulty, however, is obviously the result of imperfect growth, and will be solved by the gradual specialization of a trained class of men.

But let us return to the main question of the relation between the architect and the landscape architect. Repton, the father of landscape architecture, fully realized the importance of this question. "Where buildings are introduced," he says, "art declares herself openly, and should, therefore, be very careful, lest she have cause to blush at her interference. It is this circumstance that renders it absolutely necessary for the landscape gardener to have a complete knowledge of architecture. This remark proceeds from the frequent instances I see continually of good houses built without any taste, and attempts to embellish scenery by ornamental buildings, that are totally incongruous to their respective situations." The vital importance of selecting the best site and of fixing the grade of the first floor level is seldom appreciated. Upon it depends all consequent arrangement of details, such as the driveway approach, the house garden, forecourt and so on. And as these details in their turn affect and determine all the outlying arrangements of lawn grades, plantations and other units of the whole scheme, the importance of fixing the house grade and site is still more emphasized. Thus while all questions involving the immediate vicinity of the house should be settled in conference, yet such points as these should tend to subserve the interests of the whole arrangement of the grounds: hence Repton's position is, that while the landscape architect should have no official voice in the actual designing of the house, the style and general arrangement, location and disposition of the house and grounds should be officially determined by the necessities of the landscape architect's general plan ; for as he says further, "to my profession belongs chiefly the external part of architecture, or a knowledge of the effect of buidings on the surrounding landscape."

A similar problem, or rather a part of the same problem, points to the logical ultimate of this question. The time was when the architect was also the engineer, the painter, the sculptor, and the landscape architect. But now the architect employs the expert engineer to determine upon the necessities of construction, and to a certain extent, co-operates with the painter and the sculptor—that is, in his building he allots the spaces and positions for the mural decorator and the sculptor, and even determines the spaces and positions for the pictures. In other words, the architect confines himself to the general lines and forms and externalities of the building, while the surface and details are filled in by the specialist. Having decided these questions so as to secure an harmonious division of his general scheme, the sculptor and the painter are independent of further limitations, save that of their own genius.

Now there can be no doubt as to the soundness of this position, of the generalship and supervision which the architect has over the building which he designs. It not only provides for a perfect and harmonious whole, but it secures expert skill for each division of the whole. It needs but the extension of this principle, now universally accepted, to recognize the logical answer of the question under discussion. Here there is the added problem of the grounds. When it is a matter of large tracts of land, such as Central Park, it is no longer a question as to who shall design it. It falls naturally to the landscape architect. In designing such tracts of land, the position and sites for public buildings, statuary, and other objects of allied arts are determined and regulated by the general design. It could not well be otherwise; and it is obvious that the position here indicated applies of necessity to much smaller tracts of ground. Therefore, the logical answer to the question seems to be solved thus: the landscape architect shall decide upon the design for the whole property. For example—the units of treatment both in large and small private grounds are generally the sites for the house, stable and out-houses, and sometimes for the sculptural work; the kitchen and flower gardens, the drives and walks, and the regulations for the grades and levels of the buildings, the planting and drainage systems, and such architectural features as

*Abstract of a Paper by Mr. Geo. F. Pentecost, of New York, presented before the Architectural League of America, Toronto, May, 1902.

summer houses, pergolas and terraces. It is the business of the landscape architect to determine upon these questions, and to so regulate and adjust them that the whole will form an harmonious design. Apart from this, the architect, the artist and the sculptor are supreme in their respective departments.

There is still, however, one side of the problem which can only be solved by the mutual co-operation of the architect and the landscape architect, and that is, the character of the design for the house and grounds. It is not enough that the relative positions should be properly adjusted; the design for the house and the design for the grounds must harmonize by being based upon the same style or idea. It has been suggested that this difficulty, which is the cause of the criticism most frequently deserved when the house and the grounds have been designed by separate persons, will be solved by the specialist, who shall combine the qualities of the architect and the landscape architect. But this will not be the solution for two reasons: First, that the difficulty is more apparent than real, and can only rise under unfavorable conditions, as when one or both of the designers refuse to harmonize by compromising upon small points, or neglect to discuss the problem before settling upon the entire scheme; and second, it is directly diverse to the principle of specialization which is inevitable, and which has been the direct cause of the creation of specialists in this as in every other branch of work. The true solution of the problem rests with the progress and recognition of landscape architecture as a profession. The difficulties with which it has had to cope during its evolution are not a few. In the first place it lacks that constant stimulus and pressure which bear upon a profession based primarily on utility or necessity. Architecture is such a profession, poor or rich, a country must have its houses, both private and public, and consequently the first fruits of prosperity are drawn upon to clothe this utilitarian necessity in the garb of beauty. Therefore, the architects of a country are constantly under this high pressure which produces a high state of perfection. There is practically no fluctuation in the demand for their services, and there is a constant demand for recruits, who must be thoroughly trained in order to compete successfully. On the other hand, landscape architecture is based upon the aesthetic requirements of a class, and that a limited one; it is thus dependent upon the second or third fruits of prosperity, and is, therefore, seldom under high pressure. Its history is marked by a constant fluctuation, varying from positive extinction to comparative popularity. The result is that at the height of its prosperity, some one or two capable men appear who do nearly all the work of importance, while a multitude of small practitioners, entirely without qualifications, spring into a mushroom existence and manage to make a living upon the crumbs that fall from the rich man's table. Never has the demand been sufficiently great or of sufficiently long duration to require and to support a thoroughly trained class of men; hence the heterogeneity of its practitioners. There are so many fields with which it is closely allied, and with which it is, or rather has been, identified, that its actual nature is obscured, and for this reason it has, until recently, lacked a clear-cut and dignified position.

However, the time comes in the history of every art or craft, business or profession, when its growth, heretofore heterogeneous, becomes homogeneous. Its form gradually becomes crystallized, and its position in social or artistic circles becomes fixed. Such a time has now come to landscape architecture. Its power for good or evil is recognized, it has become in name as well as in fact, a profession of good standing; it is recognized by individual property owners, by city, state and national government; it is recognized by the allied crafts and arts, and it has become conscious of the need of self-protection. That this is so needs but the recital of a few facts. About four years ago the Royal Institute of Architects in England elected Mr. E. Milner, Landscape Architect, as honorary member of its society. This was, I believe, the first step taken by any of the allied arts to formally recognize the profession as such. In the United States, Harvard University aad Cornell and Columbia Colleges have lately introduced courses for supplying the profession with scientifically trained men. There is scarcely a city of importance, especially in the United States, which has not only its system of parks, but its official landscape architect. The fact that the United States government recently employed several landscape architects in conjunction with architects to beautify the capital of that country, speaks for itself. Again, it is the exception, rather than the rule, for private or corporate property owners to develop their land without the advice and supervision of a landscape architect. Still again, the fact that the body of architects represented by this meeting considers the subject of sufficient importance to have it represented is convincing proof that it is a subject of growing interest, and finally, within the last few years there has been formed the American Society of Landscape Architects. The formation of this society is an excellent thing; it will tend to consolidate and unify the interests of landscape architecture. It will make the profession tangible, while at the same time it will create a standard of proficiency and compel the necessary amount of specific training for its members. But in itself it is not enough. Landscape architecture is so much a part of or at least so closely allied with architecture, that whatever advances the interest of either must advance the interest of both. Until, therefore, there is not only a theoretical acceptance of this fact, but an active co-operation between the two arts, harmonious progression will be impossible. That this mutually beneficial progression is advisable is beyond dispute; that it does not exist, few will care to dispute. A spirit of antagonism has existed between the representatives of the two arts since the inception of landscape architecture, or what is the same thing, its separation from architecture as a distinct profession.

What progress landscape architecture has made during the last two hundred years, has been made in the face of considerable opposition. That this opposition has been more or less justified, is undoubted. The time has come, however, when the opposition ceases to be justified, and it is distinctly harmful to both professions. This fact is being recognized to-day and gives sufficient reason why landscape architecture is so live a subject among the architects. The fact of the matter is this. Landscape architecture has become a force in the artistic progress of modern life which cannot be ignored. And the question which arises is, inasmuch as the two professions are so closely allied, in fact, so inseparately involved; inasmuch as they, taken

STORE FRONT, KING STREET WEST, TORONTO.
SMITH & GEMMELL, ARCHITECTS.

together or separately, are practically responsible for the beautifying of both country and city life, is it not better that all animosities or rivalry between the two should be buried, and replaced by a broad minded endeavor to consolidate and harmonize the two interests? I need not apologize for speaking so frankly upon this point at this meeting, for presumably it is in the hope of consolidating the two allied arts that you have invited me here. I am the more anxious to speak upon this point for two reasons. First, because I recognize the fact that without the co-operation of the architects of the country, landscape architecture will lose the friendly aid of the most influential and dominating class of artists, not only of this country, but of all countries, for architecture is the life of all the arts, and without it all arts would cease. And second, because I recognize that the particular department of landscape architecture which elicits the interest of the architects is that class of work which landscape architecture has always slighted. I refer to the formal architectural gardens. It is my personal hope that the present revival of the formal garden will be a permanent feature in all future landscape architectural work. There is but one style of garden, namely, the formal garden, and no garden is perfect without its architectural setting. And so while I bespeak the influence of the architects of the country to advance the general interests of landscape architecture, I exceedingly rejoice in the fact that a side issue of that influence will tend to recall and make permanent in this country the undying beauty of the gardens of Italy.

ART IN THE PUBLIC SCHOOLS.

At the banquet tendered by the Toronto Architectural Eighteen Club to the Architectural League delegates last month, Mr. J. L. Hughes, Public School Inspector, had some interesting things to say about the teaching of art in the public schools of Toronto, as follows: "In our schools in Toronto, we are trying to qualify our children to understand, as well as every other department of art, literature and music. The great memorials of the past in the world of art are often the records preserved in buildings. In connection with our schools we have nineteen leagues of art, and above them we have an advisory board consisting of professional architects and artists, who give their professional advice free. So I think in that respect we are pretty well organized with the forces at our disposal. One of the things the Central Art League does is to own as many good pictures as we can and circulate them among the schools. About half the pictures we purchased this year represent great buildings of Egyptian, Greek, Roman, English, and American architecture; and last night I lectured in a school in which these pictures had been displayed during the past week. We like to find out what pictures interest the children, the teachers, and the parents. We find that the parents generally like some picture that has sentiment in it; but I was surprised last night to find that even little children in the primary school liked the front view of the Parthenon better than any other we have sent out this year; and we have sent out twenty-four pictures. You can make what you like out of that fact. This is an age of child study, and that was a revelation to me. We had pictures of sailors and soldiers, and among others a lifeboat scene to show the children what the Anglo-Saxon blood in their veins is capable of. It was a representation showing a lifeboat manned by eighteen men going into a storm that was so heavy that the boat was absolutely upended and the eighteen men fell into the waves and were drowned; but notwithstanding that another lifeboat was manned by men who had seen their comrades go down to death, and went out in the endeavor to save three men who were struggling in the shrouds of a ship. Yet that front view of the Parthenon was the picture the children liked better than any other. A majority of the teachers liked some of the cathedrals the best. I mention this simply to show that your department of art is a department that is intensely interesting. Our Supervisor of Art has for many years set the children of the schools to study the buildings of the city. This week they are to look at the porches and draw the one they personally like the best. Another week it may be a dwelling or tower. The idea is to get the little ones to look for the thing that is to them beautiful. We carry out the same idea in connection with trees and flowers. We like to encourage each child to have a tree which he loves better than any other. I think that every man should have one tree that speaks to him and stirs his soul as no other does. So we try to get the children to exercise the power of choice, and we do not tell them that what they have selected is not beautiful; for every child has a right to its own opinion, and we wish to know what is beautiful to that child this year, so that next year we shall be able to see how far it has gone in its development. We believe that true development must come from within, and not from without, in architecture as well as in every other branch of work."

Mr. Perkins, one of the delegates from the United States, said: "One of the great experiences I have had in these last three days—and they have been full of such from beginning to end—was one which Mr. Hughes gave to me yesterday morning. Besides taking me around the city, he took me to the commencement exhibit of a school of industrial design, where I saw the application of some of the principals of design we have been talking about. In the department where bonnets and dresses were made I saw sketches by young girls which we would have to hustle to keep up with. I was also very much inspired by the sight of a set of Japanese prints in that school, reproducing some of the most wonderful colors in nature, as found on the bark of trees, the slag of waste places, a bit of a mountain side, and other common objects. I saw some of the most beautiful colors reflected in a piece of bark just like what may be found in the Toronto wood. This result is achieved by the Japs because they work from the inside outward, and are allying themselves with nature, and are allowing the forces that are inherent in every one of us to find their legitimate expression."

PERSONAL.

Mr. J. A. Harvey, architect, Toronto, was married June 18th at St. James Square Presbyterian Church, Toronto, to Mary, daughter of Mr. W. C. Pettigrew, of Palermo.

Congratulations are in order and are tendered to Mr. John Wilson, architect, of Collingwood, who was married a fortnight ago to Miss Ethel Rowe, eldest daughter of Capt. Rowe, of Collingwood.

An advertiser's space in a reliable medium is the means of introducing him to a large number of prospective purchasers. On what he says and how he says it, depends to a large extent whether or not he will profit by the introduction.

THE SLATE INDUSTRY OF NEWFOUNDLAND.

As the result of differences between the proprietors and workmen at the Penhoyn quarries in Wales, resulting in the closing of the quarries some two or three years ago, the attention of Welsh quarrymen has been directed to the slate deposits of Newfoundland. Several of these deposits have been purchased and development work commenced. A Newfoundland correspondent of the Montreal Gazette writes on the subject as follows: "It looks as if the export of slate were about to become an important industry amongst us. A Welsh gentleman, Mr. O. J. Owens, arrived here on Monday last from Wales to commence the work of development on a newly-discovered slate quarry at Bay of Islands. He has a life-long experience in the work and after examining the property gave it as his opinion that it was the largest and most valuable deposit in the world. The orginal owner of the claim was R. G. Reid, railway contractor. He disposed of it to Mr. Owens on very reasonable terms, influenced principally by a desire to bring about mineral development along the line of railway and induce a large number of immigrants to come from Wales and help to build up and people this part of the country. Mr. Owens, in order to help on the furtherance of these views, has published a book on the subject of Newfoundland's slate deposits in the Welsh language, and has circulated it widely among his countrymen. The slate quarry at Smith's Sound, Trinity Bay, is now a well-established industry, and is worked principally by Welshmen, who say there is a great future for slate in Newfoundland. Last year 2,000 tons, equal to 6,000 squares, valued at $22,500, were exported. It was shipped to London and Newcastle, where a ready sale at remunerative prices was obtained. The shipping facilities are remarkably easy and vessels of any size can lay alongside within a stone's throw of the quarry, and in perfect safety. The quarry is of immense proportions and there is sufficient material in sight to last for generations".

BUILDING IN MONTREAL.

There is a revival of activity in building in Montreal this year. The increased cost of material and labor is estimated by the Building Inspector at about 15 per cent., but this apparently does not retard to any extent building enterprise, being presumably more than offset by prosperous commercial conditions. The record of new buildings since the first of the present year is given as follows: In January, permits were issued for buildings to the value of $32,615, twenty-eight for dwellings, six for stores, two factories. In February, the value was $33,500, their being thirty-five dwellings, five stores and a warehouse. In March, the value was $499,400, there being seventy-two dwellings, twenty-one stores, three churches, three warehouses and six factories. In April, there were two hundred dwellings, twenty-eight stores, three warehouses, eight factories, one office building and a church, value $536,541; in May 160 dwellings, six stores, one factory and town office buildings, value $262,240.

BLACK PAINTS FOR HEATED SURFACES.—Ordinary paints, when coated on any heated surfaces, as boiler chimneys, smoke boxes, cylinder ends, usually blister and fall from the work. The following preparation wil be found very efficient for this class of work: Procure 3 lbs. lampblack, 3 lbs. black lead, 1 lb. black oxide of manganese, 1 pint japan gold size, ½ pint turpentine, and 1 pint boiled linseed oil. Powder the black lead and mix all the ingredients well together to a uniform consistency and apply two coats as ordinary paints. This preparation will be found very durable, and will not turn white or grey when exposed to excessive heat, the same as ordinary black paints. Procure 2 lbs. black oxide of manganese, 3 lbs. black lead, 9 lbs. terra alba. Mix well together and pass through a fine sieve, then mix to the required consistency with the following preparation: 10 parts silicate of soda (soluble glass), 1 part glucose, 4 parts water. This may be used in a similar manner to the above. It is invaluable to ship and locomotive painters.

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO, of Toronto, Limited.
Publishers,
Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.
Branch Office: Imperial Life Insurance Building, Montreal.
Bell Telephone 2299.

SUBSCRIPTIONS.

The Canadian Architect and Builder will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, wil be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1902.

President	W. A. Langton, Toronto.

Coring a chimney consists in clearing it of any projections left by the pargetting. "Notes on Building Construction" says: "While a chimney flue is being built it is advisable to keep within the chimney a bundle of rags or shavings, called a sweep, in order to prevent mortar from falling upon the sides of the chimney, and after the flue is finished a wire brush or core should be passed through the flue to clear away small irregularities and to discover any obstruction that may exist in the flue."

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

BY THE WAY.

The importance of careful reading of specifications by contractors when submitting tenders was emphasized in Toronto recently. A contractor tendered for certain painting and glazing work for one of the public schools, and was given the contract. He afterwards discovered that in looking over the specification he had read "class room" for "glass room," and in consequence was out more than one hundred dollars in his calculation of the amount of work to be done. He sued the Public School Board to recover the amount, but the Judge held that he was put out of court by the contract.

× × ×

A Canadian gentleman who has lived fourteen years in Chicago, told me the other day some interesting facts regarding the municipal government of that city. He states that with the exception of the parks and the boulevards which form part of the park area, no means are adopted to clean the streets. The parks and boulevards are kept in perfect condition by the money and men provided by the county authorities and are much admired, while by contrast the streets opening into the boulevards are disgracefully dirty. In the face of these conditions healthfulness of the city is said to be maintained by the winds which constantly sweep across it, induced by differences in temperature between the low-lying sandy soil on one side and the water of Lake Michigan on the other. From this cause Chicago has been named the "Windy City." Heretofore the City Government has been largely in the hands of the saloon keepers and appearances would indicate that the revenue from taxes has found its way into other than legitimate channels. The action of several wealthy young men in offering themselves for election to the City Council is an augury of improved conditions for the future.

BUILDING CONDITIONS.

In spite of the numerous strikes which have occurred in the building trades, some of which are yet unsettled, the value of new buildings in Toronto for the first half of the present year is about three quarters of a million dollars in advance of the same period of 1901. Nearly half of the increase is attributed to the new hotel and Exhibition buildings, the remainder being principally on account of new residences, of which an unusually large number are in course of construction. A great improvement is noticeable in the new residence work both in point of design, materials, and workmanship. A large proportion of the new houses are being built for the use of the owners, being specially designed and superintended by architects. A considerable amount of speculative building is being done in localities where land may be obtained at a moderate price, but even this work is designed by architects, and is not in the same class with the shoddy productions of speculative builders of ten years ago.

It is gratifying to learn that in Montreal, where building operations have been conducted on a somewhat restricted scale for two or three years past, a revival of enterprise in this direction has set in, while the cities and towns throughout the entire country are likewise witnessing improvements on a scale in keeping with the commercial prosperity now prevailing.

It is to be regretted that workmen and employers cannot unite in an endeavor to make the most of the present favorable conditions, which cannot be expected to continue indefinitely. The numerous strikes to which reference has been made will, if continued, prove the precursor of another period of commercial depression, tempting as they do to render capital timid. We are pleased to note the general condemnation of the Plumbers' Union of Toronto for having violated their agreement with the Master Plumbers. If there does not exist a sufficient sense of honor on the part of the Unions to live up to the terms of a definite agreement such as the one in question, there is small hope that satisfactory relations can in future be maintained between contractors and workmen in the building trades.

Any kind of an advertisement may be better than none at all—but a good one is many thousand times better and costs little more.—The Advisor.

Cement Blocks.

THE new Dairy Building for the Toronto Industrial Exhibition is well worth examination by architects as an exhibit of cement block walking. It gives the Dairy Building a good architectoric appearance, and suggest the attainment of a characteristic effect, for at any rate plain work. It is rather questionable whether the right result is being attained by casting the blocks in imitation of rock faced stone; but it is remarkable how little the similarity of the blocks, which are of course all cast with the same face, catches the eye. Experience, however, teaches that this treatment will weary in time, if it does not at first. It ought to be possible to give a surface to the blocks, if that is needed, without trying to make them look like stone. If one may judge from the smooth portions of the work—the pilasters, etc., at the entrances—the edges of the blocks are what need most treatment, and attention would be well devoted to the joint.

Municipal Bungling.

WHILE the newspapers are continually urging the advantages of municipal management of public utilities and depicting private contractors in the light of robbers of the privileges and hard-earned dollars, of the citizens, the cold facts do not bear out their assertions. On the contrary, it is the case, in Toronto, at least, that every public undertaking placed directly under the control of the Council in recent years has been badly bungled and has resulted in loss of the public funds. The latest example is to be found in the new Exhibition Buildings. The contract for the structural steel work for the Main Building was awarded last February to the Canada Foundry Company, whose tender was the lowest. The Council was subsequently prevailed on to call for new tenders, which resulted in considerable loss of time. The Canada Foundry Company's tender again proved to be the lowest and was accepted. A further delay ensued while the Council listened to deputations from the Unions who wanted changes made in the specifications on which the tenders were based. This the contractors rightly refused to permit. Then changes were made in the drawings, necessitating the re-cutting of some of the structural material. As a result of these causes, two months of valuable time were frittered away, and the contractors were compelled to notify the Council that because of the delay, for which they were in no way responsible, the building could not be completed within the specified time and would not be available for this year's Exhibition. The St. Lawrence Market Building is another such example of municipal bungling. The citizens have to a large extent lost confi-

dence in municipal management of any enterprise larger than a peanut stand, and will be very slow indeed to vote for any further projects involving large expenditures under the direction of the City Council. Municipal management is perhaps beautiful as a theory, but in the light of practical experience, it must rank as a dismal failure.

The Flat Iron Building.

It is quite possible to get tired of seeing pictures of New York's Flat Iron Building, which represent it as about 10 feet through and twenty stories high. The plain fact is that this is an illusion, a representation from a trick point of view. The building is at the junction of two streets which meet at an acute angle. It has therefore converging sides, and as the point of convergence is rounded the ground plan is like a flat iron. It is in the rounded end that the interest lies for sensational picture makers. As every foot, in such a site in New York, is precious, the end is carried out to as small a round as is at all serviceable inside, and this, for the height of the building, is pretty sharp. Now, if the spectator takes up a position where he just loses sight of one side, he seems to be looking at a building which is of the size of the side in view and only as thick through as the rounded end. It all lies in the plainness of the round and in this point of view. It is just like American journalism—which regards facts only as something to be rummaged for possibilities of startling copy—to always represent the building thus, without a word. The illusion is interesting, but why not explain that it is an illusion? Something like the following would do, "This building, though in plan like a flat iron, can, by choosing a judicious point of view, be made to look like a washboard. See our illustration."

Toronto Island Park.

The latest intelligence about the Island improvements that are going to make Toronto the Venice of America, the Mecca of summer pilgrims, the convention city, is that the Park Commissioner is to take a little run of a fortnight to see what he can see and when he comes back he will settle the matter. By all means let Mr. Chambers go for a trip. He probably works hard and deserves a change. He may perhaps learn by travel what a park is like, and stop spoiling the sweeps of the Queen's Park and High Park by dotting them with his little, spikey evergreens. But what nonsense it is to talk of his taking a little trip and coming back prepared to design a park and lagoons for the island! The suggestion is his own. He accounts for his failure to produce the plan he undertook some months ago to make, by saying that he must go away first to see other places. It is a fatal error to suppose that the assembling together of ideas picked up in different places is a plan. The assemblage remains a mere assemblage even if the ideas are suitable, which they are not likely to be. At the best it is a bric-a-brac park; at the worst it is a hodge podge. What we want is a design; something that has character throughout; something that has lines; something that lies in masses; a park of which the details seem to suit itself, and do not remind one of something else. Is Mr. Chambers likely to learn to plan such a landscape by running round the parks of the United States for one breathless fortnight? Let us get down to business, by employing somebody to design who can design; and let Mr. Chambers keep in order what is designed. That is his proper business.

The Toronto Exhibition Buildings.

Now that the new exhibition buildings are in place, it is evident that they are not in the right place. The art gallery and the dairy building lie, with reference to one another, in a manner that can only be described as higgledy piggledy; and the dairy building is so placed as to cut into the axial avenue which, in the plan of the Toronto Chapter of the Ontario Association of Architects, it was shown to face. This plan was accepted and filed. It was ingeniously laid out so that the new buildings would both face the present winding roads conveniently, and yet be found properly placed, when the time comes that there is somebody in charge with larger ideas, and the avenues are widened and made more stately. The plan has been inaccurately carried out, and every deviation is an injury to the grounds. The worst offence has been in moving the main building west, far enough to set it hard upon the edge of the future main avenue. Of course the road will now have to deflect so that the building may be properly set back from it. This means that there will be no view of the lake down that avenue, as was intended, and as there ought to be.

However, the main building is wrongly placed in any case. It is easy to see now, after the walls are up, that it is out of place altogether where it is. To place a building 350 feet long so as to block, for half the Fair, the look out to the lake, which is the feature of the site, is a fundamental error. It ought to be where the old main building and the horticultural building now stand. Query: As the new building is mostly iron roof, how would it pay to take it down when the old building is condemned with its final condemnation, and put it up again where the old building stood? A better plan would be to stop the new building where it stands—the walls about complete but no roof yet on the ground—and when the Fair is over for this year make a fresh start, by pulling down the old main building and the horticultural building and moving the new main building to their site. This may sound outrageous, but in the end the $15,000 that it will cost will be well expended. The building will be put where it can be left; and, in any case, a proper arrangement of the grounds is worth more than $15,000 to the city. The question of the Fair grounds is really a serious question for Toronto, and this foolish city hall officialism which makes it impossible to get anything done properly is such a costly game that meditation naturally turns to reflect upon the comparative economy of a staff of first class, well paid, permanent officials. But how are we going to get *that* done?

The Fallen Campanile.

Evidence as to the cause of the fall of the Campanile of San Marco is accumulating and all the evidence points in the direction of a spreading strain upon the walls at the bottom. It is difficult to image how, from any other cause, the tower could collapse vertically as it did. It came down as a tall chimney that is felled by the simultaneous destruction of underpinning all round.

STORE FRONT, KING STREET WEST, TORONTO.
SMITH & GEMMELL, ARCHITECTS.

Howard Walker the American architect was an eye witness, from some distance, of its fall and describes the angel at the apex—the feature of the structure that ultimately lay the farthest from the site—"slowly descend, swaying, but upright"; and members of his family, who were close to the tower, told him that "spurts of lime-dust puffed from the tower about 20 feet up from the ground and that then . . . the base of the tower spread "like the roots of a tree?"

Another witness is an architect who writes to The Builder giving a measured plan of the Campanile which he made 27 years ago. The gist of his observations is that the inner and outer shells, between which runs the sloping ascent vaulted in brick, were tied together by wooden bond timbers some of which were decayed. "In many cases" the timbers were cut out, he supposes on account of decay, and had not been renewed. He noticed "several serious cracks in the structure", which he "attributed to the decay of the bond timbers".

Further evidence is given by the ruins themselves which show:—first, that "large numbers" of the bricks were old bricks—Roman bricks, stamped with a stamp which identifies them as coming from Altinum, a city which was ancient when Venice was new—; and, secondly, that the walls were badly built, in some cases being mere shells,(those jerry building ancients again!) filled in with rubbish.

When one thinks of an inclined plane of brick 3 feet 9 inches wide and 875 feet long (by this English architect's plan) resting its accumulated weight at the bottom upon walls which were badly built of bricks which had already served their term a thousand years ago; which have been suffered to decay behind the concealment of a marble loggia and have been deprived by decay and careless cutting of their wooden vaulting tie; it is no wonder that the base of the tower spread "like the roots of a tree."

THE R. I. B. A. COLONIAL EXAMINATIONS A CHANCE FOR ARCHITECTS.

There is seldom anyone who has had a liberal education who does not later in life wish that he had the chance again, knowing what he now knows of what kind of study would be the best for him to pursue. If it were possible for men to take up their calling for some years before finishing their education there is no doubt that the finishing process would be done more intelligently and with greater interest and profit. Architects of all men find that practice opens their eyes not only to new fields of study but to the need of more careful study of what they have already learnt. In particular is it true that increasing experience inclines them continually to the study of the academic examples. Whereas in their younger days they were apt to think a general acquaintance with the historical styles was all that was desirable for this country, and that more intimate study was better expended on current examples; as they increase in experience, it is current work that receives only general attention and they long, generally in vain, for time and opportunity to study old work even out of books. It is not impossible, even in the midst of practice, to pursue these studies to some effect, but it would require much energy and more method to accomplish anything systematic. A day's work does not create an appetite for evening studies, and without a definite end within sight there is little chance but what these studies will be indefinitely postponed. With something to fix a limit both in time and in extent it is easier to begin and to keep going. Here then is a use for the Colonial Examination of the Royal Institute of British architects.

The examinations consist of two days given to a sketch design; it was an almshouse in the examination of this year. After this there are papers on the following subjects:

1. THE NATURE AND PROPERTY OF BUILDING MATERIALS; their decay, preservation and quality, and their application in building.

2. THE ARRANGEMENT AND CONSTRUCTION OF BUILDINGS, in relation to health, drainage, water supply, ventilation, lighting and heating.

3. SPECIFICATIONS AND ESTIMATING. A specification of the work in various trades. The measurement and cost of building work. The conditions for building contracts.

4. CONSTRUCTION. Foundations, walls, retaining walls, arches, vaults, floors, roofs, etc., and constructive details in all trades.

5. CONSTRUCTION. Construction in iron and steel. Showing underpinning and dealing with ruinous and dangerous structures.

None of these papers would afford much difficulty to an architect. Any practising architect ought to be able, we may gather from these examination papers, to go into the examination hall without preparation and pass with sufficient credit. He might perhaps also pass in the remaining paper—6. THE PRINCIPAL STYLES OF ARCHITECTURE: their features, mouldings, and ornament, so that if the right to put A.R.I.B.A. after his name is all he wants the only thing that need stand in his way is the five days' effort necessary and the six guinea fee.

But this paper upon the architectural styles is worth more to Canadian architects than to be merely an instrument for acquiring letters. It makes the very motive that is wanted to stimulate to continuous application in the study of historical work. The ultimate goal—freedom of design—is not less surely attained if the attention is fixed for a time upon the examination as an intermediate object. The examination, like a half way house, will make the way seem shorter. But its prime use lies in its supplying a fixed line of study and a fixed time for its accomplishment. These are a great help to a lonely student.

If the loneliness could be got over a greater difficul y still would be removed. Association is always a help to students, and will be particularly so to the architect student who has other work to do and to whom it is desirable that this course of study should present as much as possible the appearance of recreation. Why should it not be made something of the nature of recreation, by a number of architects agreeing together to take the examination and meeting together once a week or so to talk over and analyze the characteristics of the styles? Both the Ontario Association of Architects and the Province of Quebec Association have attractive rooms, with conveniences for associated work, and, examination or no examination, this is the sort of work to do there.

There is more reason for meetings of this kind than

CANA... ...ER

merely to give to solitary work the pleasure of society. Association in study both broadens and quickens apprehension. "Iron sharpeneth iron; so a man sharpeneth the countenance of his friend." Several pairs of eyes means several points of view, and united research and united criticism will get to the practical essence of the matter more quickly than solitary study. Moreover it is remarkable how much easier it is to remember what has been enjoyed in common than what has been enjoyed alone. The person who, in reading Shakespeare for the first time, observed that he indulged largely in quotation, would never have been so familiar with these passages if he had read them first for himself. One may read

MR. A. McDONALD,
President Winnipeg Master Carpenters' and Builders' Exchange.

and enjoy without remembering; the thing to fix a passage in the mind forever is its application by some one else to point an idea. Common study will contribute in this way to a common stock of knowledge that is clearer, more vivid and more practical than any member of the body could attain to alone. There is likely to be noticeable results in the way of vigorous design proceed from such a group of associated artists.

It is as artists that architects will meet one another in such a field of work as this, and it seems to be a law that capacity in the individual artist develops only by association. Solitude may nurse reflection, but art is execution and needs contact with the effort of others. The best work in art has always originated from a group of artists. The diverse results in individuals of a group show that association does not weaken character. Artists cannot suck one another's brains. Each man's ideas must grow in their own way, but they grow best in an atmosphere where thought is free. If a school of architecture, however local, could grow from united effort in study, so much the better. We suffer for want of unity; from the dissipation of effect that comes from individualism; and if by any possible means we could attain to such agreement of type in any town that excellence in a building would consist not in being different from its neighbours but only in being more excellent, we should have a town that would have architecture, no matter what the type.

This is looking a little onward from the R.I.B.A. examination, but study of originals and asspciated effort are two things which are apt to go far in results.

SOUTH AFRICAN TRADE.

With the ending of the war in South Africa will come a period of great development in that country and a consequent demand for many lines of manufactured goods. German and Austrian syndicates are said to be forming to exploit the South African market. With cool audacity the continental countries which indirectly supported the Boer cause and obstructed the British, are now seeking to reap the commercial advantages arising out of the conditions established by Great Britain at an enormous cost in men and money. The United States have also been exporting largely to South Africa, and their trade returns for the first half of this year show a substantial increase above the same period of 1901. It seems only fair to her own interests that Great Britain should impose some restrictions in the form of duties on foreign goods entering the South African market, thereby giving a preference to home and colonial industries, which will have to bear a considerable portion of the expenses of the war, and compelling foreign countries to contribute something for the commercial advantages which are the direct result of the long continued and successful struggle conducted by Great Britain. Canadian exporters of manufactured goods should lose no time in establishing trade connections in South Africa, and should be properly represented at the South Africa, British and Colonial Industrial Exhibition to be held in Cape Town from November to February, 1903-4.

Building materials, especially bricks, lumber, doors and sashes, and structural iron and steel are in large demand. The United States have already secured some valuable orders in this line. The establishment by the Dominion Government of a direct freight service between Canada and several of the principal South African ports is a gratifying assurance that this country proposes to secure its share of this trade.

Most of the business must be done through importing agents. Lists of these in the principal towns should be secured, personal letters addressed to them acquainting them thoroughly with the character of the goods to be offered. Exporters should also be prepared

MR. A. McCORMICK,
Secretary Winnipeg Master Carpenters' and Builders' Exchange.

to send samples and submit tests of their materials, as in many instances these will be demanded. Care should be taken to ascertain the financial responsibility of all firms with whom correspondence is opened, before sending goods forward, especially in the case of commission firms among whom there are many "sharks," who make their living out of "consignments". The principal demand is for goods of medium quality and moderate price. Whatever the quality of goods for which orders are secured care should be taken by the exporters to maintain uniformity, otherwise they may not expect to hold the trade.

STORE FRONT, KING STREET WEST, TORONTO.
SMITH & GEMMELL, ARCHITECTS.

THE FALL OF THE CAMPANILE.

The most satisfactory account, which we have so far observed, of the cause of the recent collapse of the Campanile at Venice, is that given by Dr. A. Robertson, a clergyman residing in Venice, who is understood to be the author of some valuable historical works. Dr. Robertson has written a series of letters on the subject to the Edinburgh "Scotsman", in which he states that in 1892 Luigi Vendrasco, associated with the building, reported to the Government the necessity of immediate repairs. Subsequently, a Government commission was appointed to examine the structure. This commission reported that no repairs were necessary. Because of an urgent protest by Vendrasco, the project to install an elevator in the building was abandoned. Later on Vendrasco was removed from his position because he persisted in urging that the Campanile should be strengthened. His successor, a young draughtsman, caused to be removed a line of drip stones extending the whole breadth of the east wall of the Campanile, with the purpose of inserting a band of zinc to prevent leakage from the walls of the Campanile entering the adjoining Loggetta. This is said to have weakened the wall and to have lead to its ultimate destruction. Dr. Robertson sums up the cause of the failure of the building as follows:

(1) Though the walls were thick, thicker, indeed, than I said, for they were not five feet thick, but only a few inches under six feet, they were really not solid. They consisted of two parallel walls of brick, the space, three feet wide, between them being filled up with broken bricks, rubble, cement, stones, etc. Therefore the walls were not so strong as they looked.

(2) The cement used was Istrain lime mixed with sea sand. This lime does not become hard, nor does it adhere well to the bricks. Indeed, in the course of the past centuries it became dry powder. It is all over Venice to-day. It formed the cloud that hid the falling Campanile.

(3) It has been damaged by lightning, by fire and earthquake several times. On June 7, 1398, it was struck by lightning. In 1401, on the occasion of festivities for the Doge Michael Steno, fires were lighted on the platform, and the top was burned. On October 24, 1403, the same thing happened. In 1405, the same thing happened. In 1417 it was struck by lightning, and the new top of wood again burned. On June 21, 1436, all the shops around the Campanile built against it were burned. On March 26, 1511, an earthquake split its four corners. In June 1548 it was struck by lightning. In 1565 it was struck by lightning. On July 10, 1591, an earthquake caused it to shake from top to bottom. In 1653, again struck by lightning. On August 23, 1657, again struck by lightning. On April 23, 1745, again struck by lightning, which damaged its east side serverely, killing many people in the Campanile and near it. This was its last and most serious damage, although it was not till June 18, 1776, that the Republic employed the scientist Guiseppe Toaldo to put up a lightning conductor.

(4) The Republic, seeing its east side to be severely damaged, consulted two engineers of fame and ability, Signor Zandrini, of Venice, and Signor Polene, of Padua, to examine and repair it. These engineers said the whole wall wanted support, and they proposed building a new wall against the old one. This was done. But the new wall was never properly tied to the old one. The two were practically separate, and so the weight of the Campanile was borne unequally, and its equilibrium disturbed.

(5) The ringing of the bells, the firing of artillery, and only three weeks ago the simultaneous firing in the Piazza of hundreds of muskets had a tendency to disturb it. Also the more or less frequent earthquakes that visit Venice.

(6) Twenty years ago one of the corner pilasters of the inner wall, and precisely that at the north-east corner, was seen to be cracked in many places. The authorities of St. Mark's Church, who have charge of the Campanile, as it is the bell-tower, had this pilaster tied up. No more cracks appearing anywhere, the Campanile was thought perfectly safe, and was let alone.

(7) And now comes the critical point. The Loggetta, little marble hall, built by Sansovina, rests against the eastern wall of the Campanile. It had almost a flat roof. To prevent the rain beating against the Campanile and running down its side from entering this marble hall, a row of slabs of stone sloping downwards was inserted in the Campanile where the roof met it.

(8) Only last week, that is, but ten days ago, these stones were begun to be removed, as the rain was somehow getting into the Loggetta, and a lead sheeting was to have been substituted. Instead of carefully removing one stone at a time, they removed half of them—that is, twenty five feet of them. Not only so, but they dug through the new wall of the Campanile, that of 1745, and struck the old original wall, which they found separate from the new, and full of holes and cracks. Whilst working, the old wall slipped down an inch or two. Instantly the cut made was built up, but it was too late. On Wednesday the 16th, it was observed that the new wall was cracked at the north-east corner, above the Loggetta, where the work was begun. On Thursday it enlarged. On Friday it struck across the north-east side of the Campanile, sloping upward to the second window from the ground, then up to the third. On Saturday it passed behind the fourth and through the fifth. On Sunday the situation was, to use the word of an engineer, "desperate," and the Campanile was doomed. On Monday the crack visibly opened whilst we watched it, and the end came in a moment, when the whole structure sank into itself.

The city authorities are censured for having disregarded the repeated protests of Vendrasco, for having permitted the public to approach and enter the structure after the approaching collapse was evidenced by cracks extending from top to bottom of the angles of the walls, and for having neglected to save the precious bronze statues, bronze doors, and marble carvings in the Loggetta. The doors have been found among the debris, also two of the pictures on the ceiling, one by Veronese and the other by Schiavoni. The porch of St. Mark's Church was saved from destruction by a very thick column of red porphyry which stood in front of it, and against which was hurled a huge piece of marble adhering to a mass of brickwork. After the disaster, which fortunately resulted in no loss of life, all the shops were closed, and the city was given up to mourning. A large number of subscriptions have been received for the rebuilding of the tower. The only sufficient reason for rebuilding would seem to be to preserve the most ancient and valuable features of the original structure.

ARCHITECTS AS BUSINESS MEN.*

There exists a belief, as vague as it is general, and possessed of all the tenacity of an agreeable religious faith, that the practice of the architectural profession, that is to say, the designing of buildings and supervision of their construction, is a fine art; that it consists of certain mysticisms, executed largely with pencil and paper, and is governed by an intangible something held rigidly fast by fixed recipes, either of ancient tradition or of modern schools, which must not be contravened; that the architect is a fantastic dreamer, and ability in design and capacity for business are fatally antagonistic qualities, and impossible of friendly association in the same brain; that architects, in order to be good architects, must be steeped in an intoxication of ornamental forms, made respectable by old age; with minds almost closed against progressive thought, and above all, without disciplined mentality or ordinary business habits.

Also that an architect is in some manner a picture maker; one who can tell plausible lies in perspective, or in rendered elevations with accurately cast shadows, with equal facility, and that he may ignore every tenet of manners, customs or of common sense which all other men following any other profession or business, are bound to and do respect. In short, that the architect is a creature of moods and emotions, and as these elements have neither responsibility, quantity nor standard, he is, therefore, himself unaccountable, unsubstantial and unreliable.

This is pretty much a delusion, and although I am aware that it is a dangerous thing to disturb comfortable beliefs for the substitution of disagreeable facts—things which involve readjustment of personal philosophy, and contain a promise of work ahead, because the fallacies are harmful and the causes of conditions that are deplorable and injurious to the profession and its practitioners, and constitute obstacles to the progress of art which are otherwise insurmountable—they ought to be exploded.

The first fact is, that instead of our successful architects as a whole constituting a class of befogged dreamers, they are in reality fully as keen and of as large capacity in the business of money-getting as any other constituency in American affairs.

As we cast our eye over the personnel and work of the architects of the country, of whom it may be said that they have achieved success, we find the number of those successful by artistic qualities alone a minority, so small as to become relatively a negligible quantity. Upon the other hand a large majority have achieved worldly distinction as successful architects purely because of business capacity. In other words, the practice of architecture over which the profession, as such, has not control, has been a business rather than an art. In this connection it is perhaps proper to say that there is also a distinct class of practitioners who, owing their successes primarily to social position, make the simple error of ascribing their successes preferably to artistic merit. Of course, without the quality of business acumen upon their own part, or upon the part of friends or family, the presumed artistic merit would have remained long in obscurity. The only point made here is that these instances should evidently be connected with the majority of business successes rather than otherwise.

While there have been, and are, architects who adhere to the pet delusion before recited and others who have conveniently indulged it for business profit, there are also those who with great sincerity make not the slightest pretense that their successes are founded upon anything other than superior business ability. Of these it may be said that they have no delusions at all, and deceive neither themselves nor others. They were and are business men engaged in gaining money by practising the business of architecture. They employed men of such artistic ability as were to be found, as their business demanded such, and paid them well. Now, there are those who affect to believe that there is something in this last condition which is wrong and reprehensible. I do not share this belief. I can not find reason to reproach those who achieve success because they are forceful business men, provided that they practice their business under fair and honorable methods and do not sail under false colors. I prefer to learn something from the evidence furnished by those examples af many of our architects whose names and works become familiar.

The deduction which I make is that the ordinary belief of a successful architect's composition is a delusion, and that business capacity on the part of the architect, under the organization of modern society, is a prerequisite to his success, and consequently to the progress of architectural art.

The reason for this is quite apparent. The architectural opportunities fall to those who are preeminent for business rather than artistic ability, and thus it is they who build the architecture of the country—good, bad or indifferent. The architect must be a business man first and an artist afterward.

*Paper read by Julius F. Harder, Architect, of New York, before the New Jersey Chapter of the American Institute of Architects.

THE POWERS OF ARCHITECTURAL ASSOCIATIONS.

The Philadelphia Chapter of the American Institute of Architects expelled one of its members for having taken part in a competition in the face of a resolution of the Chapter which condemned the conditions and declared that any member who should become a competitor would be guilty of unprofessional conduct. The offending member applied to the courts to compel the Chapter to reinstate him. The Court upheld the contention of the plaintiff that in passing the resolution the Chapter had exceeded the powers granted by its charter and that its powers were restricted to those specified by its charter. According to this decision associations of professional men are without disciplinary powers, and must therefore be the more careful to enquire into the character of the men they may be asked to admit to membership.

In view of the value of wired or prism glass in windows as a protection from fire, on buildings where fire shutters would not be tolerated, Insurance Engineering suggests that their design be carefully considered by architects, with a view to making them more sightly. The design of the embedded wire might, for example, be made in an ornamental pattern and the size and shape of the prism glass frames be varied to relieve the present monotony. The reduction of the hazard incident upon the installation of these devices is so marked that they are certain to come into very general use, and a consideration of their æsthetic appearance will assist largely in their rapid introduction.

PLANNING.

Plan may be treated under several heads, such as (1) axia arrangements, (2) location of rooms, (3) accommodation, (4 hygienic condition, (5) artistic arrangement, or the fine ar principles of planning—all important points to keep in view. The first of these, the arrangement of axes, is a fundamental condition of the planning of all large public or private buildings, but few architects make it a study. The main axis of a building ought to have a relation to sight and aspect. In an elongated site with the narrow frontage to the main street, there would be one axis passing through the entrance hall and through the larger apartment as a council chamber or public hall, while if the site is of large area, and extends laterally as well, there may be two axes crossing at right angles, one at right angles to the front, the other parallel to it extending laterally in one or both directions, and upon these two axes the architect may dispose his chief rooms or departments. The relation of these lines or axes to the aspect or points of the compass will not of course hold in town sites; but for country residences the main axis of the chief receptioo-rooms ought to have reference to those points of the compass from which the most desirable light and sunshine are to be obtained. In the planning of hospital pavilions, asylums, and the like, the importance of sunlight and genial winds is recognised, and in many of our latest hospitals, as that of the Grove Fever Hospital, Tooting, the large pavilions are placed axially due north and south, the effect of which is to secure a south-east aspect and a dry atmosphere to each pavilion or ward. Another axial arrangement is to place the pavilions due north-west and south-east. The architect should make a study of the aspect compass in laying down his plans for buildings of this description. In arranging his windows in domestic buildings it is equally important that he should bear in mind that for morning sunshine the windows should look eastward, for evening sunshine westward, and for evening coolness eastward. It is, therefore, of value that his principal rooms should be so axially placed that their windows may face as nearly south-east as possible. But the main axes of a plan may be determined by other considerations—to obtain a good view or vista from the main entrance, or a suite of apartments, having reference mainly to the interior effect. We only mention the value of an axial distribution that will afford the best aspect, if possible. Not less of moment is the question of outlook. In many buildings, as rounty residences, the main axes of rooms may be determined by a pleasant prospect—hence the importance for the architect to determine the position of his chief rooms on the site before he prepares his plans.

Rooms may be arranged axially in several ways, the two axes being placed at right angles instead of parallel; thus the rooms may be L or T-shaped, just as the axis of one meets that of the other. This gives rise to various juxtapositions of rooms, parallel side by side, or end to end, axially as above, or they may be disposed en echelon, one room projecting before the other. Another way of arranging the main rooms is to so unite or join them that one fits into or interlocks with the other, as when a recess of one room projects into the other, so that both have recesses, but in opposite ends. All these methods are employed in planning to give variety, and to produce external breaks.

The location of rooms is probably the first consideration with the architect, even before he can devote attention to their axial arrangement. Having fixed the position of his main and other entrances and the principal aspects, he sketches out roughly the principal rooms or departments of his plan. This is a work requiring both skill and patience, and probably several attempts are made in pencil before a final decision is made. In actual planning the student will find the sectional paper divided into squares of the scale he adopts of great use and help in massing out his scheme. Under this head there is little that can be said, as each problem of planning has its special location of rooms. The plans we see of houses, schools, municipal offices, and baths convince us how little is systematically done. The novice has one notion of planning: he draws an entrance, and a long corridor leading from it, and places his rooms one by one, regardless of shape or convenience, along this line; but the skilled designer likes to break up his area, to shorten his corridors as much as possible, and to place his main rooms in their positions before he commences to consider detailed requirements. He adopts certain axes upon which his larger rooms are placed, and, in fact, axial arrangement and location of apartments are concurrently worked. His plan presents a scheme of orderly grouping of departments all within easy access of one another, and he attains compactness and concentration with the least labor or indirect means. Other plans show a "beating about the bush"; a want of study of the requirements of the scheme. We at once detect this in awkward positions allotted to some rooms, circuitous corridors, and bad lighting. The scheme as a whole has not been grasped; the best positions are assigned to inferior offices and the like. Every experienced planner can detect almost at a glance the want of principal coherence, and grouping exhibited in a plan. He can, in fact, almost immediately say whether the designer knows anything about the requirements or not. A want of grouping and classification is evident in most novices, plans. They are scattered, disjointed, and regardless of wall supports in the upper floors; but we are not now considering construction, but simply planning, though we would here say there is one real quality in good planning, and that is, it is constructive.

Accommodation, our third point, is too important to be considered in one article: it implies a large acquaintance with statistics and data, the allotment of space or area for special purposes of building as for assemblies in halls, churches, and theatres, floor or seat area; bed and desk area as for hospital wards and schools; all of which involve a study of the leading authorities—hygienic, medical, and other—on these respective subjects. We know of plans for workhouses and schools that have been thrown aside owing to the ignorance of their designers about the area per bed and per pupil allowed in such plans by the Local Government Board and School Board. Without a knowledge of the floor area required in each case, it is impossible to lay down a plan correctly. We may roughly locate the room, but such rough arrangement must be adjusted or modified by actual dimensions before we can complete the plan. In a large building—say, public offices, or a public school—the readjustment may practically necessitate a larger area, or some of the rooms being placed on another floor. No one as yet has thought of compiling areas for different purposes of building, although certain data have been published to aid in estimating buildings such as hospitals and schools by the bed or per scholar. Yet there are certain areas accepted and used in planning that have been authorised, such as the space allowed for each bed by the Local Government Board, or area of floor for each pupil by the Board of Education. The rules for elementary schools are by no means fixed. In the United Stated, for instance, the classrooms in the best schoolhouses of recent construction are about 32ft. long and 28ft. wide, and 13½ft. high, and accommodate 56 pupils seated at single desks, which gives a floor area of 16ft., and an air-space of 216c.ft. for each pupil; but it is recommended by one authority that a classroom should be 32ft. long 24ft. wide and 15ft. high, to accommodate 45 pupils, which gives an area of 19ft., and a cubic space of 250ft. per pupil. In England, classrooms generally are planned to allow 10ft. to 14ft. superficial per pupil—a rather wide limit. In churches, a floor area of from 7ft. super. per sitting to 10ft. or 11ft.; but these figures include the aisles, lobbies, sanctuary, vestry, and choir, and, therefore, do not help the architect much in planning the seated areas. The actual floor-space per sitting is about 4½ft. to 5ft. superficial—that is, allowing the usual dimensions for each seat, or, say, 3ft. from back to back of seats, and 2uin. to 22in. for each person. Nearly every authority publishes its own rules for seat or floor area. Thus the London County Council, under the Metropolis Management and Building Acts Amendment Act, provides for theatres a seating area to each person of not less than 2ft. deep and 1ft. 6in. wide in all parts of the house where no backs or arms are provided, and not less than 2ft. 4in. deep by 20in. wide where they are provided. This allowance is little enough, and only provides per floor area 3ft. to 3ft. 8in. The London School Board and the Local Government Board have their regulations, which the architect has to consider before he can settle upon the plan.

The hygienic conditions of planning have also to be considered. We mean by these the requirements of light and air, ventilation, warming by artificial means, &c. These are matters that we need not discuss here; but the relatinn of doors and fireplaces in residential rooms is not always attended to as it ought to be. We have seen plans and houses in which the living or reception room has its door on the same side as the fireplace—often near the fireplace-wall at one corner, and even more frequently in the wall opposite the fireplace—of all positions the worst, as when the door opens those seated near the fire are at once exposed to a current of cold air, and are immediately exposed to the view of any gazer who happens to be in the hall. It is rather strange that so many architects ignore the right positions for doors both to sittingrooms and bedrooms. How

SMITH & GEMMELL, ARCHITECTS.

often we enter a bedroom in which the bed is exposed to view from the outside, instead of being placed with its head to the wall in which the door is; but there is no other wall against which the bed can be placed. The simple rule that the door should screen the bed or the fireplace as much as possible is disobeyed, and the inmates exposed to unnecessary draughts or the gaze of the inquisitive.

In our limited space we cannot dwell at any length on the last head of our subject, artistic arrangement, or the fine-art principles involved. Everyone will have noticed, in going over a number of competitive plans, that some are architecturally arranged—that is, the authors have complied with those amenities of plan that go to show them accomplished designers. Great solicitude and care will be shown in the arrangement of the entrance-hall and staircase, in easy, well-lighted vestibules and corridors; and even in the plan of each principal room the author will not sacrifice the convenient approach to his room; it will be well lighted, and be proportioned by a regard to a pleasing ratio of length to width and height; he will study, too, the arrangement of his ceilings, their divisions into compartments by pilasters, by making little adjustments in the positions of his rooms and entrances. Such proportions of drawing-rooms will be found as 18ft. by 22ft., or of dining-rooms as one-and-a-quarter to one-and-a-half times the breadth in length. Then variety and charm will be given to the location of the principal rooms by avoiding square or merely rectangular shapes, and making recesses and bays or L-shaped compartments, which can be managed often by fitting one room into the recessed part of another in the manner we have before mentioned. The pleasure derived from pursuit, or from not seeing the whole of a room or hall at once, immensely increases the mystery and charm of the interior. Other points on which we cannot now enter—such as bay windows, ingles, the arrangement of furniture, &c.—are matters that come under this head, and which may be all made to contribute to the sense of homeliness and comfort.—Abstracted from the Building News.

PUBLICATIONS.

It would be difficult to devise a more persuasive setting forth of a university course of study than is shown in the Biennial Review of the School of Architecture at the University of Pennsylvania. Confessedly planned upon new lines for the purpose of presenting a comprehensive account of the character and environments of architectural training at Pennsylvania, the Review sets forth in detail the requirements of the course from the entrance examinations to the completion of the fifth or "Graduate" year. To this end, typical problems have been selected whose demands are printed in full together with one or two of the best solutions offered in each case by the students. The course in Interior Decoration is represented by schemes dealing with rooms as a whole and by several charming individual pieces, such as furniture, wall papers, lamps and other decorative objects. Supplementing all this work are the courses in drawing from the cast and from nature, the latter especially being represented by several excellent studies in charcoal and water color. The nature of the work done in the related fields of history and building construction, as well as in those more purely academic studies which are essential to a well rounded university course, is of such a nature as to preclude its pictorial expression. The details of these studies are given in full in the text. A limited supply of copies of the Review may be had, while the supply lasts, by enclosing one dollar to the Bursar of the University of Pennsylvania. The book contains about one hundred pages of text and illustrations, the former in a special poster type on hand made deckle edged paper, and the latter on dull calendered paper for the half tones and inset on a special paper for the gelatine plates.

NOTES.

The Gold Medal of Honor of the Royal Institute of British Architects has this year been awarded to Mr. Thomas E. Colcutt, F.R.I.R.A., architect of the Imperial Institute building in London.

Some of the most recently constructed buildings in Paris have cut in the stone facade the name of the architect and date of erection. In passing by one of the best modern examples of good building in a Canadian city we noticed the date deeply cut on the corner stone and wondered why the name of the architect did not appear also. Canadian architects should adopt the French practice in this particular. Their names would thereby be perpetuated, the public would be informed to whom the credit for designs of important and well designed buildings should be given, and an incentive would be given architects to put forth their best efforts in design.

Mr. Harry Hems, the veteran sculptor of Exeter, in a letter to The Building News, states that the chair used for King Edwards' Coronation is a new one designed and made in Paris. He remarks that "the 'design' shows an armchair such as Litchfield would scorn to have shown in his 'Illustrated History of Furniture,' and with nothing individualized about it save the Royal Arms, which occur in the upper part of the back, completely overweighted by a royal crown half as heavy again as it ought to be for its surroundings." He prophesies that visitors from the United States will get duplicates in Paris for their dining rooms at £15 to £20.

The planning of people's baths depends, says Mr. Walter W. Thomas in a paper on the subject, chiefly on the shape of the site available, but as the hall and rooms required may be of any form no unsurmountable difficulties will be experienced with any ordinary site; care, however, ought to be taken to have the arrangements as symmetrical as possible. It is advisable that there should be two entrances, one for either sex, leading into a waiting hall, from which access to the baths is obtained. The bath hall ought to be in sections or blocks, so arranged that they may be used for males or females as required. Should there be ample room at disposal, the size of the dressing rooms would not be too large if made 4 feet by 4 feet 6 inches, and the bath-rooms could be the same size. The minimum size of either rooms should not be less than 3 feet 6 inches by 3 feet 3 inches. The corridors may be from 4 feet to 6 feet wide; 5 feet is a fairly good width if the corridor is not more than 30 feet long.

Whatever may be the criticisms passed on many of the decorations which blossomed forth in contemplation of the Coronation, it seems to be generally agreed says The London Building News, that in the Canadian arch our Dominion friends have produced a novelty, as much by reason of the design as in the lesson which it has sought to convey of the resources of the great colony's territory. Sturdily square, two very tall towers of stout wooden beams rise from the carriageway of Whitehall, allowing passages on each side, between them and the pavement, of the width of a vehicle. They are joined by a massive, very simple arch of wood. On a level with the top of this emerge from the summit of the two towers high white poles, six on each, supporting pointed roofs. The arch, the upper outline of which is perfectly straight, has on its centre an octagonal roof, reaching considerably above the other two, and resting, as do the latter, on white poles. The form of the whole structure is simple, but its best feature is the harmonious colouring. The towers and the arch are entirely covered with plaited straw, fixed by red flowers. Wheat, oat, and barley sheaves are looped round the edge of the roofs. The arch is decorated with plain curved lines of twisted corn on some shiny, crimped stuff of a cherry red. Above, in letters of the same red on a yellow ground, are written the inscriptions, "Canada, Britain's Granary," and "God Save our King and Queen."

Some time ago the well-known French sculptor, Bartholdi, described in La Nature a simple method of ascertaining what dimensions of a proposed monument will produce the desired effect on a given site. A silhouette of the design is cut from cardboard, either a scale drawing or preferably a photograph from a scale model furnishing a basis therefor. If this can be tinted so as to give the tone of the material to be used, so much the better. The silhouette is attached to one end of a piece of soft wire, which is wrapped loosely round a cane, umbrella, or other similar support, so that its position may be shifted back or forward at will. On the site of the monument, just alongside where the base will probably come, is placed a vertical measuring rod marked off into prominent divisions. The experimenter takes his position at a sufficient distance to secure a good general view, and brings up to the level of his eye the support carrying the silhouette, aiming as with a gun towards the site. By shifting the position of the silhouette along the support it may be determined after a while where it produces the best effect, considered as furnishing the illusion of the original structure. By there noting the correspondence in height between any given division of the small design—as, for instance, the top and bottom lines of the die—and the feet or yards on the measuring rod, a scale can be established. This scale applied to the drawing or model will show what the sizes of the executed work should be.

VOLUME OF WATER IN HOT-WATER HEATING APPARATUS.

The volume of water required per square foot of radiating and heating surface, in the radiators, mains and heater of a hot-water heating apparatus, for best results in heating and greatest economy of fuel in operation, is a question which has received some attention in the past, but judging from the differences of opinion, as expressed in their various constructions, by manufacturers of heaters which have been used for heating by hot water during the past twenty-five years, and which are being offered and used at present for that purpose, we are still far from a standard, particularly in the volume of water required in the heater per square foot of heating surface exposed to the fire or heated gases.

In the manufacture of radiators, particularly when they have been constructed with a view to their being used for hot-water heating, the standard aimed at, and finally accepted by the leading manufacturers of radiators in this country, has been one pint of water to the square foot of surface—being approximately the volume of water contained in one square foot of surface of one-inch, ordinary thickness, wrought-iron or steel pipe.

Some radiators have been constructed which contained less than this volume of water, and some which contained considerable more, but in either case these radiators have gradually gone out of use, while new designs in hot-water radiators which have been brought out during the past six years, have largely conformed to this standard, which seems in practice to be the best suited for this purpose for all classes of buildings, except, perhaps, all-glass constructions, in which I have found it to be an advantage (on account of the greater and quicker cooling effect in such constructions, and the variable temperatures at which the water in the system is sometimes maintained, on account of irregular firing, lack of fire-box capacity or lack of capacity in the heater, and on account of friction due to the long lines of piping usually employed in placing the required radiating surface in this class of building) to use a surface that contained from fifty to one hundred per cent. more water, although were a uniform temperature maintained in the water in the heater, and the same arrangement of radiating surface utilized that is at present used for the heating of other buildings with this system, with short circulations, and an ample arrangement of mains, it would not be necessary to increase the body of water in the radiating surface above one pint to the square foot of surface.

CANADIAN PAVILION, WOLVERHAMPTON EXHIBITION OF ARTS AND INDUSTRIES.

At our last annual meeting, during a topical discussion, when this question was under consideration, I mentioned an experiment or test made some years ago, in two green-houses of uniform construction, size 16x100 feet. Each house contained approximately 2,000 square feet of glass and had about 650 square feet of surface or running foot of 4-inch greenhouse pipe; each house was heated by a separate heater located in the same pit, with separate brick flues 8x12 inches, extending 20 feet above the ground. To these flues each heater was separately connected by 10-inch wrought-iron pipe; each had about 4 square feet of grate area and about 90 square feet of fire and flue surface (about half fire and half flue.) The radiating surface was arranged in the usual way for such constructions in 4-inch greenhouse pipe on each side of the house, below the benches, with one flow and two return pipes on each side; an open expansion tank at the extreme end of each line, and each side connected separately to the heater with 4-inch flow and return connection. In one house the 4-inch pipe was left regular and had an internal area of about 10 square inches, in the other house 2x2-inch oak strips were inserted in the centre of the pipes, reducing the waterway about 40 per cent., while retaining the same external surface. In a six-hour test maintaining a 60-degree temperature in each house with an outside temperature of from 25 to 30 degrees, an average temperature of 160 degrees was maintained in the flow mains and 130 degrees in the return mains at each heater. The consumption of fuel was 130 pounds of anthracite coal, stove size, for the house with full waterways in the radiating surface, and 110 pounds of the same coal for the house with reduced waterways, while the temperature on the flow main on the heater with reduced waterways was frequently 5 degrees higher than on the other heater, and the dampers on this heater had to be partially closed to prevent a higher temperature. Later this house was lengthened 25 feet, or 25 per cent., and piped in the same way, and the temperature maintained with the same average consumption of fuel as that used in the other heater with 25 per cent. less surface and glass area.

Since that time I have used largely 1¼-inch pipe, with a little over one pint of water to the square foot of surface, in small conservatories; 1½-inch pipe, with about 1½ pints of water to a square foot of surface, in medium-sized conservatories, and a 2-inch pipe, with about one quart of water to the square foot of surface, in large conservatories and greenhouses in preference to 4-inch greenhouse pipe with about half a gallon of water to the square foot of surface. I have found that I obtained better and quicker results, a greater possible variation of temperature, and greater economy from the use of 2-inch pipe, with manifolds, than from any other size of pipe, either larger or smaller.

In arranging the mains of a hot-water heating apparatus the area of the main has to be determined from the number of square feet of radiating surface to be supplied and the nature of the surface, whether direct, direct indirect, or indirect radiation, and from the length of the main; also, whether the main is to be used as radiating surface or covered, so that no standard as to volume of water per square foot of surface supplied could be adopted in regard to the mains in a hot-water heating apparatus without being subject to considerable variation. At the same time I have found cases in hot-water heating where the area of the mains was from 25 to 50 per cent. larger than was necessary, and they could have been reduced with beneficial results, being made large to insure a uniform temperature in the main, which could have been obtained in a smaller main with a different arrangement of taking off branch connections.

The greatest difference of opinion as to the volume of water required per square foot of surface in hot-water heating seems to exist in the heater, or source of supply.

Beginning with boilers of the Cornish type, which are used in some sections for hot-water heating, they contain about three gallons of water per square foot of boiler surface; then the ordinary horizontal and vertical tubular boilers, arranged for hot-water, have about 1½ gallons per square foot, a number of cast-iron one-piece and sectional heaters have about one gallon per square foot, some have three quarts and others half a gallon; then some heaters of this type, and water-tube heaters, contain from three pints to one pint per square foot, and in some heaters constructed of one-inch pipe, while the volume of water to the foot of surface is not materially reduced, the friction is increased by inserting a sheet of metal, as a circulating division, reducing the pipe to half its area. Now, if we do not consider the Cornish boilers, which are more largely used in other countries, and begin with the horizontal tubular boiler, which is largely used in this country, we have a variation in hot-water heaters of all the way from 1½ gallons to 1 pint of water per square foot of surface, and while all of these different constructions, with their varying amounts of water, will accomplish certain results with more or less efficiency and economy, certainly some will produce better results than others, and on that account would be considered a proper standard; and while the arrangement and location of the surface relative to the fire and heated gases would make some difference as to the volume of water which

*Paper by Mr. M. Mackay read before the American Society of Heating and Ventilating Engineers.

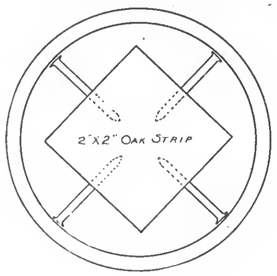
should be back of it, I have obtained the best results from an average of a half-gallon of water per square foot of heating surface in a hot-water heater, with an average of from 20 to 25 square feet of heater surface to each square foot of grate area, the surface being arranged with about 50 to 60 per cent. of fire surface and about 40 to 50 per cent. of flue surface.

DISCUSSION.

Prof. Carpenter: The paper is to be commended as bringing out a great deal of information about the relation of surface to volume, both in radiators and in boilers, and this ratio is an important factor in the successful operation of the radiator or boiler.

If the volume be too small within the boiler the circulation is likely to be bad, particles of steam are thrown out, and the results are poor. With too large a volume the action will be slow, and there will consequently be an excessive demand upon the apparatus.

C. B. Thomson: In manufacturing boilers we have to make one type answer for both steam and water, and we have to pay particular attention to the fact that it is a steam boiler. There are many little problems in a steam boiler, such as carrying a steady water line, carrying a water over into the radiators under certain conditions, and we have to be careful about the waterways and the return column, so as to get good circulation. On that account boilers are sometimes made to contain much more water than would be desirable in a water heater. I believe the



most popular heaters in the market to-day contain about one-half gallon of water to the square foot of heating surface.

If manufacturers built boilers for water alone, ignoring the conditions required for steam boilers, they would produce more efficient water boilers. A hot-water boiler requires small waterways and a large amount of effective heating surface exposed to the direct rays of the fire; also a rapid circulation of the water It is generally known, and I have made experiments which prove it, that with a sluggish circulation, sought to be accelerated by a strong draft, the draft carries away much of the value of the fuel. An easy and rapid circulation is therefore essential.

Mr: Mackay: I would like to enlarge on one subject a little On account of the sun greenhouses require little or no heat during the day time. With 4-inch pipe you must waste your heat to the outer air by opening ventilators during the day. With 2-inch pipe you can lower the temperature more quickly in the morning and avoid opening the ventilators and wasting the heat, and ye you can quickly raise the temperature to the desired point in the evening when it becomes cooler. At our last meeting something was said of the advantage of storing heat, but I think it better to generate heat as you require it and use it as you generate it.

Some people object to hot-water heat in dwellings because it takes too long to raise the temperature in the morning. I have not found it so in properly placed and properly operated apparatus.

The President: Do you use an open or closed heater?

Mr. Mackay: Always open. I can get better results with an open system, and I consider it dangerous and bad to use high pressure when you can do the work with low pressure.

Prof. Carpenter: The question as to volume and surface really comes down to a question of circulation. The smaller the volume on a given amount of work the greater must be the circulation, and it has been pretty well proved that the greater the circulation the greater the efficiency of the surfaces, both of the boiler and radiator. So it really comes down to what is the least practicable limit in velocity of circulation. Personally I favor a large volume of water in a hot-water heater for heating houses, as tending to reduce fluctuations of temperature. We like to put on a fire and have its effect distributed over a long time.

FIRE-PROOF BRICKS.

Theoretically, the ordinary types of bricks made by the clayworker are fire-proof; but, practically, very few of them are. We, of course, exclude perforated bricks in making this statement, says a writer in the British Clayworker. During a conflagration of any magnitude, the inside bricks, especially in partition walls, usually become red-hot. This leads to the expansion of each brick concerned, and buckling of the walls commonly results. This effect is minimized where the mortar has been laid on thickly between each brick-course, as the coefficient of expansion of ordinary builders' mortar is not the same as that of the bricks. In the last-mentioned case the mortar is, in the vast majority of instances, ruined by the great heat at an early stage of the conflagration, though if the wall is a thick one the mortar in the interior of the wall may to some extent be preserved. Cement mortar does not seem to be so much affected as ordinary lime mortar. Where the life of the mortar is sapped, so to speak, the bricks suffer more from the heat, but the greatest amount of damage is done to them by the water from the firemen's hoses. The sudden application of cold water to a hot brick frequently has the effect of cracking it, particularly if the operation be of an intermittent character, which is generally the case. In order to test the quality of a brick for fire-proofing purposes, therefore, it is desirable, amongst other things, to heat it to as high a temperature as possible, and then plunge it suddenly into a bucket of cold water. It should not be allowed to remain there more than say 10 to 12 seconds, and should then be returned to the retort, or whatever the form of furnace in which it was heated for the experiment. This procedure is rather drastic, and many types of bricks cannot withstand it; but it certainly brings out their relative capacity for endurance under extreme changes in temperature. In watching such experiments it will be noticed that whilst many different kinds of bricks crack and split right across, others will simply have a corner or two removed, and a third may merely exfoliate. In the last-mentioned instance the bricks are usually of very fair quality for the purpose. The sudden application of the water to the red-hot surface produces steam, which in its turn exercises a semi-explosive result at innumerable points on the surface. The accumulation of these points locally leads to "starring" and frequently to serious exfoliation.

It is difficult to lay down a law as to what should constitute an ideal brick for fire-proofing purposes, but it is clear that cæteris paribus one that does not become red-hot very quickly, and which does not expand much, should fall into the first rank. At the same time, the brick must be strong, especially for the construction of of buildings in which much ironwork is employed. For, whilst it is in itself being very severely tested during a conflagration, the brick has frequently to bear the brunt of an attack from the iron girders. These latter expand very much during a conflagration, and though when properly built up an allowance is made for this, they are apt to buckle and exert enormous strain on parts of the wall not designed for such contingencies.

Bricks that are not protected in any way by fire-proofing materials, and upon which reliance is solely placed, ought not to be of a soft character except for small buildings where there is no likelihood of a very high temperature arising during a fire. The reason we make this exception is that they are less liable to great expansion during the fire, though they must first have been thoroughly well burnt in the kiln. We exclude nearly all fire-bricks from these observations.

STORE FRONT, KING STREET WEST, TORONTO.
SMITH & GEMMELL, ARCHITECTS.

BAGSHAW V. JOHNSTON.—Action brought in the High Court of Justice at Toronto. Solicitor for defendant Siddall moved to dismiss the action as against the applicant on the ground that no relief can be obtained against him for the cause of action alleged against him in this proceeding to enforce a mechanic's lien. The defendant Johnston is the owner of the property on which plaintiff asserts a lien, and the defendant Siddall was the architect for the owner. This proceeding or action was begun by statement of claim under the Mechanics' Lien Act. The claim is to enforce the lien and also reform the contract between the plaintiff and defendant Johnston, and to set aside the defendant Siddall's certificate or for damages. Held, that defendant Siddall is not a necessary party to an action to realize a lien, for he is neither a contractor nor a wage earner, nor one who has supplied materials, nor is he an owner or encumbrancer. He is merely the architect for the work. If plaintiff wishes to proceed against him he is of course at liberty to do so, but he must not do so under the Mechanics' and Wage Earners' Lien Act, for no power is given to join such a claim under it. Order made striking out the name of defendant Siddall as a defendant, with costs to be paid by plaintiff. Leave to defendant Johnston to make any motion that he may be advised.

Discoloration of a newly plastered internal wall may be due to several causes, but we should hardly blame the bricks. It may be caused either by the composition of the backing or of the setting coat, by the floating having been brought up in one coat, or because there was insufficient thickness in the coats. Two or more of these may have united in discoloring the surface. The only remedy is to replaster, using good materials and in three coats—described as render, float and set.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

Brick Fences.

BRICK fences which are so common a feature in England, have not been employed to any large extent in Canada, although the use of brick in conjunction with wrought iron for this purpose is noted in some recent work by Canadian architects. One difficulty which is said to attend the use of brick for this purpose in Canada, is that one side of the fence may be more subject to dampness than the other, leading to unequal expansion and contraction of the material, and ultimately to the toppling over of the structure. The use of cement instead of lime mortar in work of this character might prove a remedy.

The Preferential Tariff.

THE news comes from Berlin that the German customs authorities will in future require certificates of origin in the case of American grain. This is regarded as a retaliatory slap at Canada for having granted preferential duty on British goods coming into this country. The Dominion should now demand a certificate of origin in the case of all imports from Great Britain. This would have the effect of shutting out large quantities of German goods which now find their way into Canada as British imports and get the benefit of the preference which was intended to apply only to British manufactures. The statement is made on what appears to be good authority, that many German manufactured goods are shipped into England, where the assembling of the parts is done, after which the goods are exported to Canada and receive the benefit of the preference. At present there is nothing to prevent such a practice either by Germany or other countries. Means should be adopted to prevent the preference being accorded to any but bona fide British goods.

Province of Québec Association of Architects.

THE Council some months ago passed a resolution recommending that the Association establish a Scholarship for Students in the Architectural Department of McGill University. It is proposed that this scholarship should consist of a sum sufficient to pay the fees of the successful student during his four year's course. The action of the Council requires ratification by the Association. Two meetings of the Association were called for this purpose, but much to the regret of those who had interested themselves in the matter, the necessary number of members to form a quorum could not be got together. The matter will therefore come up for consideration at the annual meeting in January, when it is hoped the proposal will be approved. Meanwhile, by reason of the apathy of the members, the proposals, if adopted,

cannot go into effect until the opening of the winter term next year. The establishing of a scholarship of this character should awaken a deeper interest by the students in the study of Architecture, as well as in the P. Q. A. A. and the work of the Architectural Department at McGill.

A Peculiar Objection.

THE ways of the trades unions, like those of the heathen Chinee, are sometimes peculiar. News of what appears to be the very latest cause for a strike comes from Grand Rapids, Mich. The union bricklayers of that city have refused to work on a building because the foundation walls are constructed of cement and are carried up a few feet above the ground level. Members of the union state that the action was taken because of the effect the use of cement as a building material will have on their trade, the new construction not requiring the services of skilled bricklayers and stone masons, and threatening, in case of the universal adoption of the cement construction, to deprive them of a large part of their employment and thus drive them into other fields. It is a foregone conclusion that this action must fail to seriously retard the use of cement for building purposes. The adaptability of the material tor foundations and for the entire construction of certain classes of buildings, such as warehouses and factories has been so far established that its extended use in this direction in the future is assured. On the other hand, it does not seem probable that it will become popular in the construction of residences and other buildings in which a high standard of architectural effect is sought for. After all, therefore, its effect on the employment of bricklayers will probably not be serious. In any case the unions will not be permitted to dictate to owners, architects and builders what materials they shall employ in the construction of buildings.

A Uniform Size for Bricks.

A correspondent writes that the table on page 110 of the new edition of the Canadian Contractor's Hand Book, showing the number of bricks in walls of various thicknesses, will not apply to bricks manufactured in Toronto. This is no doubt true, but the table is correct for some other localities, as for example the Maritime Provinces. Our correspondent's complaint again draws attention to the fact that there is scarcely any limit to the variations in size of bricks manufactured in this country. As an illustration in point, an architect who has some work in progress in a northern town writes "I am putting up a block of stores, and because of the brick famine in this section, I am compelled to use three makes of bricks—one from Barrie, another from Stayner and the third by a local manufacturer. No two makes are alike in size. This causes a great deal of trouble in bonding." The three manufacturers from whom this architect obtained his bricks are distant from one another not more than fifty to sixty miles. It will thus be seen how sizes vary even in what might be considered the same locality. In short each manufacturer appears to be a law unto himself. In another column will be found a table similar to the one in the Hand Book, but based on the largest size brick made in the Dominion so far as we can discover. This may be of some value, but from what has been stated it will be seen that no table that could be compiled would meet the requirements. Steps should be taken by the government or by the Architectural Associations and Builders' Exchanges to compel Canadian manufacturers to adopt a standard size for bricks, and put an end to the inconvenience arising from existing conditions.

City House Exteriors.

WIDE differences of opinion exist among architects with regard to what must be considered important features of their work. A discussion took place recently among members of the profession with reference to the outside appearance of city dwellings. A certain well-known house in Chicago was cited, which in the opinion of one architect had more the appearance ot a prison than of a residence. The answer was that the interior of this house was entirely satisfactory and that the windows and doors faced upon an attractive inner court. Some of the parties to the debate contended that the exterior of a house facing the street might be of almost any character; that the owner and architect were not under obligation to make the exterior of such a building pleasing to the public; that the main requirement was to make the interior satisfy the desires of the owner. Others strongly combated these views, and held that in order that cities might be pleasing and interesting, it was necessary that attention should be given to the exterior treatment of residences as well as other buildings. Against this opinion was cited the American style of street house, which is so designed as to convey the idea that the occupants live, to a large extent, on the street. This style of house has large porches and verandahs, bow and other windows set low so that the interior is plainly visible from the street. There is something to be said in favor of both sides of this question. Perhaps the solution lies in the architect taking a middle course—that is, in making the outside of the house as attractive as the funds at the disposal of the owner and architect may permit, without in any way sacrificing the interior. It is undoubtedly proper that a dwelling should afford those who occupy it the necessary privacy, but it does not therefore follow that it should present to the observer from the street the sppearance of either a barn or a prison.

OUR BRITISH OFFICE.

Owing to increased British business, the publishers of the CANADIAN ARCHITECT AND BUILDER have established a branch office at 22 Grand St. Helen's, London, E. C. Persons interested in the building trade are requested to avail themselves of the facilities thus afforded for securing information regarding the demand in Canada for constructive materials. Our representative will be pleased to call personally in response to a request. Address the C. H. Mortimer Publishing Co., 22 Great St. Helen's, London, E. C.

In Prussia the Minister of Public Works has determined to prescribe by circular the necessary rules which are to be observed for the proper control, in manufacture, of the qualities of cement. In future every depot will be required to have a test office. The tests will not make it impossible for any but a specialist to carry them out; a knowledge of the use of the instruments and reagents will be all that is necessary. This knowledge can be acquired in either the State laboratory or in one of the cement works. Thirty pounds is to be advanced to each depot for the purpose of buying the necessary instruments, which are to be of the same pattern as those in the Charlottenburg laboratory.

A DOMINION EXHIBITION.

At the Toronto Industrial Exhibition last week the Hon. Mr. Tarte spoke of the desirability of holding a Dominion Exhibition, and of holding it at Toronto, as a good central place, already possessed of an experienced organization capable of carrying such an exhibition out. Mr. Tarte's promise to personally endeavor to help forward such an exhibition may be taken to mean that he does not ignore the question of cost. A Dominion show will require Dominion money, and its advocacy by Mr. Tarte may be considered as bringing the matter within the sphere of practical politics.

The idea ought to be taken up with energy. On the question of general expediency there is no douot that it s a great idea, having incalculable possibilities in the way of developing trade within our own borders. We do not know each other well enough. There has been a rush of development in this country of late years that requires just such an opportunity as an all-Canadian exhibition to enable the different provinces and sections of the country to become acquainted with the nature and extent of each other's productions. We are apt, both in buying and selling, to think first of other countries, because we have not yet learned to expect our own country to supply us with either the products or the market we want. By dint of successes in the World Fairs of other countries, we have learned that the fruit and dairy products of Ontario rank first class in this planet. Our fisheries have long been a main support of the Roman Catholic church, in Europe as well as in this country; and we have recently came to regard ourselves as one of the granaries of the world. Our northwest is indeed rapidly enabling us not only to sell wheat to the world, but gold, to buy it with.

Yet these are but specialties; points in which we range ourselves with other countries. There are, besides these commodities, plenty more, which ought to be as well known inside the country. It is only a few things after all that a nation can expect to supply to other countries; but it ought to expect to supply itself with all but a few things. We give each other the least possible encouragement. We say Canadian manufactures cannot afford to be first class because they have not the market to justify it. The market is here; gaping for first class articles; but importing them from the United States.

It is just such a state of affairs that a national exhibition of national productions will tend to rectify. For such a chance producers will produce their best, and we shall be able to see if we have not in our own country not only the necessaries of life—food, clothing and fuel; but also its luxuries—books, plumbing supplies and objects of beauty.

Of course such an exhibition will do us no harm with the outer world. Canada is a great country for summer visitors from other countries, and Toronto is apt to be a place of call for most of them. To say nothing of the summer conventions, which find it a convenient and pleasant meeting ground, Toronto is in the way of Americans fleeing for July and August to our north-west fishing rivers and to Muskoka; and it is near Niagara, which European visitors must see before they can face their friends at home. With a Dominion Exhibition going on, these visitors would "stop off" and "take in" the show; and more would come because there was a show to see. All of which would be good for trade, both present and prospective; and would no doubt, sooner or later, pay the cost of the exhibition. But the idea which appeals most to the imagination and suggests the greatest possibilities is the national stock-taking and interprovincial acquaintance-making that would take place; giving openings for trade, or producing at one stroke a market, for which both producer and purchaser have long been ready if they had only known of one another; a grand national courting bee to promote marriage between industry and trade in our family connexion.

To take one example which is of interest to readers of the CANADIAN ARCHITECT AND BUILDER: There is abundance of building stone in Ontario; limestones, sandstones, granites, gneisses, serpentines and marble. Specimens have been collected by the Bureau of Mines and made a striking exhibit at the Pan-American Exposition. Yet for these stones we go to Indiana, Ohio, Scotland and Italy; and for all that can be seen at present will continue to go there indefinitely. Here is one sort of product that our deserted waterways might very well carry, and there is nothing so likely to cause them to do so as a National Exhibition, well carried out.

This brings us to the aspect of the question which is more within the province of this journal than the question of the general advantage of holding such an exhibition. If done it must be done well; and in that need lies the chance of Toronto redeeming its lost opportunities in the way of both grounds and buildings for its Industrial Exhibition. It is at these grounds that the Dominion Exhibition will naturally be held. But while the Toronto Industrial Exhibition Association is no doubt the best available means of putting it on foot, the grounds of the exhibition are not only inadequate—a defect easily corrected by the juxtaposition of the extensive vacant military ground by the Stanley Barracks and the filling in which it is proposed to do on the lake shore—but, to have any adequacy at all as a mere portion of the show, the grounds will require an upsetting and reconstruction from which they will never recover; and that is what they want. It is such a chance to get things pulled down and things built that is not likely to occur again for many years; for the Park Commissioner, though stout, is temperate, and apparently healthy. Would he were a worse man, and had a better imagination! The grounds of the Industrial Exhibition, regarded as fair grounds, are just about as near nothing as they can be. An annual visitor has still, every year, to think before he can find his way to the grand stand. As for finding his way from it—there is but one way for everybody, and that in the wrong direction. Happy is the suburban Parkdaler who alone, when the fireworks are done, gets home to bed, undegraded (and unbruised) by crushing in a street car. There ought to be an eastern exit connected with either trams or trains; and the necessary accomplishment of such additional exit for a big Exhibition might be made one of Toronto's permanent gains proceeding from the Dominion show. But these, through important considerations, are quite secondary to the absolute want of effect in the present fair grounds. The plan is mere confusion. There is no leading idea, no visible arrangement, no attraction for the eye. These wandering roads with incoherent

SMITH & GEMMELL, ARCHITECTS.

buildings on them make no recognition of the fact that, a Fair is after all a great out of doors assembly; that people are out of doors most of the time and want to find their pleasure in being there. By making proper effort a Dominion Exhibition might be made an occasion to change all this. Its principal court would suffice for the main portion of the permanent Toronto Fair; and matters should be so arranged that the buildings round this should be made permanent and the court designed to be sufficient both in size and beauty to make the Toronto Exhibition what it should be.

Mr. Tarte's proposal that the Dominion Exhibition should be held next year leaves too short a time to do the thing properly; on the other hand it is hard to do anything that will take two years to do, on a ground where an Exhibition is held every year. But there are preparations, drawings contracts, ironwork, etc., that would be all the better for having a year, or all that is left of it after getting under way; and the filling in of the lake front might also go on at once. It would be cruel to shorten the Street Commissioner's enjoyment of such a happy dumping ground for ashes to one brief year. Besides there is going to be a shortage of ashes this year. With one year to advance preparations as far as possible, and a season of great activity, the thing might be done for the June after next. It would take this time, also, one would think, to make sure of good exhibits.

If it is to be accomplished so soon as this there is no time to be lost, and even if it is given another year there is no occasion to delay taking the preliminary steps.

BY THE WAY.

Referring to a crusade which has been started in Dundee against the defacing of buildings by smokers striking matches against the walls, the London Builders' Record points to the necessity of using for walls which are liable to defacement from any cause, materials which are proof against disfigurement. Glazed or glass tiles or bricks will meet this requirement in many positions.

× × ×

In remodelling the Union Loan Building, Toronto, Messrs. Burke & Horwood, the architects, have adopted the American plan of designating the ground floor as the First Floor, the floor above as the Second Floor, etc., and have so numbered the rooms as that the room number shall indicate the particular floor on which it may be found. For example, on the first or ground floor the rooms number from 10 to 19, on the 2nd floor from 20 to 29, on the 3rd floor from 30 to 39, etc. The numbers of the several floors are shown in bold figures on the sides of the elevator.

× × ×

The residents of a London street in which a large building was in process of construction appealed for and were granted an injunction restraining the contractor from operating a derrick before 7 a.m., on the ground that it spoiled their slumbers. The contractor did not let the matter rest there, however, but carried the case to the Court of Appeal, which discharged the injunction. The court held that there was no vested right which secured people living in a residential street from being disturbed before 8 a.m. It was to the interest of everyone to have the work executed as quickly as possible. The contractor also submitted the plea that he was under penalty to complete the building by a given date.

× × ×

The members of the Institute of British Clayworkers hold a yearly excursion and visit in a body places of special interest where combined with pleasure information of value to the trade may be obtained. The practice is a commendable one. This year a visit was made to the clayworking districts of France. In this connection the British Clayworker remarks: "The trade in brickmaking is a long way behind England as a whole. There are comparatively few facing bricks made in France, and those chiefly in the Burgundy district, which we did not visit. The common brick trade is, generally speaking, of a very inferior stamp, but those made at Vaugirard were of a very fair quality, and the fire bricks made at Boulogne were excellent. The glazed bricks made at Ivry cannot compare with those made in England by the best firms, but they were excellent bricks, and the question arises whether the perfection and costliness of the English article is justifiable or necessary for ordinary purposes. We should be inclined to think that a product equal to that of Ivry would find an immense market at its relative price in this country. The French tile is undoubtedly a very superior product and worthy of extensive imitation. It is universal on the Continent. It is cheaper and lighter than the plain tile and more ornamental. It is cheaper and cooler than the slate. Some very good work is done in terra cotta, but it has not the pretensions of English architectural terra cotta. The use of it is undoubtedly limited by questions of cost, and it is only on very superior buildings that the architectural stoneware produced at Ivy could be introduced."

STAINED GLASS.

At a meeting of the Sheffield Society of Architects and Surveyors Mr. A. Jeffery delivered a lecture on "Stained Glass," in which he said that the first stained glass executed in England was in the time of King John. Previous to this all glass came from Italy, which even at this date boasted of eminent artists. The old masters taught us many lessons, and much could be learnt from them. We should try and embrace all the good qualities of the old men, ignore their shortcomings, and try to improve on what had been done before us. After the sixteenth century stained glass died out, and did not again revive until the nineteenth century. Mr. Jeffery went on to explain that a window should be part of a building, and should not be treated as a picture or wall decoration. If a man attempted a picture he spoiled his material as glass and made a very bad picture. The lecturer described the different methods of manufacture. He said that English glass was superior to foreign, both in material and workmanship. The most important point in a window, in his opinion, was permanency, and only the most permanent of colours should be used, at whatever cost. Speaking of domestic glass he did not think the modern style was a passing fancy, but that it had come to stay, but like all other transitions in art at the outset it seemed to have been let loose, and we appeared to be seeking after something we could not quite grasp. But the style would ultimately settle down and find its own level. He was eagerly looking forward to the time when there would not be so much commercialism in connection with artistic crafts, and hoped architects in the near future would come more into contact with the craftsmen, and by their joint ideas succeed in raising the standard of work.

OFFICE FORMS FOR ARCHITECTS.

We have received from Mr. Walter Chesterton, architect, of Winnipeg, a copy of a form of certificate which he has used for some time past and has found very satisfactory. We take pleasure in reproducing the form herewith for the information of our subscribers to whom we trust it will be found valuable. In this connection we would be pleased to receive from architects copies of any office forms which they may have proved to be particularly adapted to their requirements, as well as particulars of office methods generally.

THE USE OF COLOUR.

Considerable regret is felt by many of the older members of the A. A., that colour is being so little studied by the students of to-day. The primary cause is, no doubt, that there are already so many subjects which must be taken up for the examinations; but I am inclined to think that, behind this, there is also the consciousness that it is a big subject in which the way is not very clear, and in which the results, as seen in the experience of their elders, are apt to be extremely uncertain. The student sees examples of the introduction of colour, by good men too, which he cannot bring himself to think are of much advantage to the building though not without harmony in themselves, nor wanting in attractive quality as to design; and he is puzzled as to what to study, or what to admire. And the real fact is that, as a "Handmaid of Architecture," colour is neither properly studied nor even properly looked at by the majority of architects. One has but to turn to the papers read and the discussions on them to realise that the attention is all given to points of method or medium, or to questions of hagiology ar archaeology, all matters interesting in themselves, but only in a secondary degree of importance to the architect's work. It is hardly an exaggeration to say that even the harmony of colour itself is, for the architect, a study of secondary importance; for he may obtain assistance in that when it comes to the execution; but it is of the first importance for him to know and understand what colour can do for his building, and how. This means that he needs to study and understand not so much particular harmonies and contrasts of individual hues, as the general principles on which the placing of colour of different values depends, to influence the ultimate effect of the whole interior, that is to say, as influencing the architecture. This is what really concerns the architect, and it concerns him just in the same way as the sections of his mouldings or the position of his carved detail concern him—they are all matters vitally affecting the general impression which his building is to produce.

Let us then endeavor to see what should be the attitude of the architect towards colour. Firstly, he wants to be sure that his building will gain by the use of colour. It will certainly gain if the colour helps to explain and adorn it without disturbing the sense of repose, or if it, perhaps, assists in producing repose. Observe that the quality of repose has nothing to do with the "medium" to be used or the "subject" to be introduced. It has to do with simplicity of expression in all that concerns the suggestion of stability. Now colour, properly placed and of proper value, can greatly assist simplicity of expression, even amidst much elaboration; just as it can also annihilate simplicity. This is almost entirely a matter of judicious placing of the colour values; that is, so adjusting them that those structural forms which express stability, are first recognized, and that features of secondary importance are not the first to attract notice or to compete for attention. This does not imply that colour is to be lavished on the structural features—far from it. The end may be often attained by leaving them almost plain; but it means that they are to be constantly in mind, and that whatever is done with colour must be so done as not to set up an interest at variance with, or detracting from, the structural expression. This is not an empirical statement, it is a sufficiently obvious general law; but it receives extraordinarily little attention from those whom it most concerns; for in its application, it is not only less simple than it appears, but it is capable of infinite variety.

When the colour decoration of an interior has to be considered, it requires to be studied in the first instance much as a picture would be, as a whole; and, as with a picture, although some special scale of colour may be intended, it will be better in most cases to think it out, or plot it out in monochrome; for so the mind will be less embarrassed by a multitude of problems at

one time. At starting, what we have to decide is which lines or features are essential to the expression of the building, and how these can best be maintained as a connected whole. In some places they will need accentuating, in others rather blending or connecting with adjoining surfaces—for we do not want a harshly defined network or skeleton of construction exhibited—we want to recognize the bony structure, not to have it shown detached from the muscular tissue. All this and the main features of ornamental treatment can be best worked out in black and white; for by this it is more easy to see where force is required, where to be avoided; and the effect of awkward or ungraceful lines is more easily recognized. It is only when the scheme has reached the point where these general requirements have been satisfactorily adjusted, that the question of rendering it into colour need be taken up. Of course with lengthened experience, the practised colourist arrives at the result by a short and mental process.

Now the rendering into colour of any scheme of decoration naturally demands not only a knowledge of colour, that is of the effects of colours on each other and of their harmonies, but it also demands considerable experience in the use of colour for decorative purpose, where each colour has to be used point-blank, without the shadings and modulations which play so important a part in the colouring of a picture. And, besides this, experience can alone prepare even a good colourist for the extraordinary changes to which his colours are subject between the palette and the surface to be decorated. No one who has not the experience can be in the least prepared for the amazing pranks which reflected lights can play on colours; nor for the almost equally astonishing influence of the tones prevailing in the proximity of the parts under treatment. These are matters which cannot be learnt at the desk or the drawing board; and for that reason, if for no other, the execution of the scheme in situ needs the experienced hand if it is to succeed. But a much more limited experience may succeed in projecting an excellent scheme, if only guided by a true architectural sense; and when I said above that a knowledge of the harmony of colour was, for the architect, of secondary importance, what I intended to imply, and what I think will be seen is that such knowledge, however desirable, and however essential for the full working out of a colour scheme, is less necessary for the architect than the perception of the nature of the aid to be looked for from colour; and that, whilst few can have the time or the opportunity to gain such a knowledge of colour as would enable them to prepare and carry out a whole decorative scheme, most architects can, if they will, train themselves to see how and in what form such decoration can be of service to their building. Careful observation and the habit of analyzing the motives in good examples, and the value of the results obtained, will by degrees render the student much more confident as to the direction in which he must seek success in his own works.

The study of colour, if a man has any developed sense of colour, may be carried on day by day, by observation or by practice, in a dozen different ways. Sketching, whether from landscape, from flowers, or from example, is all good study if done with the mind awake to understand the lesson. In sketching, we have to grasp the fact that each colour is affected by others near it, and that its value is relative, not fixed. We have to learn that the foliage of the tree which comes into our subject cannot be represented by the hue of its individual leaves, but by the different hue produced by the many thousand lights, shadows and reflections of its many thousand leaves, qualified too by the tones of adjoining objects and by the interposed atmosphere. Similar lessons are to be learnt in sketching from flowers, in the doing of which the student will soon find that the charm of his subject and its harmonious contrasts largely depend, not upon the direct contrast of a brilliant flower with an individual leaf, both equally lit, but upon the contrast of the bright flower itself enriched by some shade, with foliage tones qualified by shadow and reflection. His sketch, if it does not catch these facts, fails of its colour lesson. When it comes to the application of such lessons to decorative colouring, as harmony, the student has to remember not what was the "local colour" of flower or leaf, but what tones of colour produced the harmonious effect, so that when he sees his sketch at home, in a diffused light, he still has some equivalent of the original charm.

For the study of the application of colour, decoratively, the great school is Italy; but before a man can profit by it he must have some amount of mental training, and have done something in the way of cultivating his powers of analysis; that is to say, he must have learnt not only to recognise what is good, but why it is good; and to be able in some degree to understand what the artist aimed at. Perhaps only by degrees will he arrive at appreciating the subleties by which the end was attained: for these, like the master touches in a picture, are only to be recognised by one who has himself made some progress. But the broad principles and general motive can be understood by anyone whose architectural instincts are true, and can bring an unprejudiced mind to study them. At the same time he has to be on his guard against confounding executive merit with decorative excellence; for it is only too true that as the former grew the latter tended to decline. In Italy, moreover, the really good work is often swamped by a vast quantity of later bad art, frequently so bad as to discourage the student from his search for the good.

There is another, collateral method of studying colour decoration, which is interesting in itself and affords valuable training too. It is the habit of regarding every interior in which one may happen to spend a little vacant time, as a possible subject for colour treatment. In the intervals of a concert, between the acts of a play, or during the delivery of some after-dinner speech, to try and think out carefully a scheme of colouring for the place in which you would otherwise be suffering ennui, is at once a diversion and profitable study. You have to be your own critic and to ask yourself "Why?" at every step; but the habit gives a useful grip of the way of looking at the subject.

The study of colour, however, once pursued, has a constant and ever new attraction which grows with the pursuit. The architect who does not heed it leaves one side of himself uncultivated, and loses one joy in life; his buildings lose a part of their possible charm, at any rate within; or sometimes, by later inconsequent or unskilled treatment, lose all.—J. D. Crace, in A. A. Notes.

CANADA PAPER CO. SMITH & GEMMELL, ARCHITECTS.

UNIFORMITY IN SPECIFICATIONS FOR CEMENT AND METHODS OF TESTING.

The attainment of a standard specification is greatly desired by all those called upon to use cement in works of construction; indeed, this matter is of such importance to the manufacturer and consumer that both are concentrating their efforts in endeavouring to accomplish this result.

Mr. Lesley has given us much interesting information in regard to the great variation at the present time in specifications for cement, these variations not only arising from differences of opinion between experts as to what constitutes good material, and from different methods of testing, but also arising in many instances from lack of knowledge or from inexperience. Some of the specifications call for high strength, others for low; some require quick and others slow setting; many require a finely ground product to be slow setting and to be low in sulphuric acid, which is difficult and often impossible to produce; others introduce chemical qualifications which, if not submitted to an expert for approval, often impose very unnecessary restrictions on the manufacturer.

The difficulties under which the manufacturer labours are therefore evident. His material must satisfy all of the specifications of his different contracts, and a single product can scarcely be controlled by subsequent treatment to meet these different requirements; also he is sometimes asked to meet impracticable conditions. The advantages of a uniform specification to a manufacturer would therefore be great. Instead of being obliged to meet irrational and sometimes impossible specifications requiring a great variety of grades of material, he would be required to produce only one, or possibly two, grades, one quick and one slow setting. His work would be greatly simplified, which would not only reduce the probability of producing inferior material, but also tend to reduce the cost of production.

The advantages of uniformity in specifications, moreover, are by no means entirely in favor of the manufacturer. The material would be ground to a certain fineness, have a definite specific gravity, and develop a strength with less range of variation when treated under definite conditions. Thus the consumer could depend upon the quality of his material better than he does now, and would consequently be able to use it more understandingly, by adopting more efficient methods of manipulation and more economical designs. He would also be able to establish the fact when failures in mortar and concrete occur from poor workmanship and improper manipulation of the materials rather than from the inferior quality of the cement, and he would apply such remedies as would secure more durable and permanent structures. The investigation of cement in any one branch of construction would have a definite bearing on all cement construction and could be utilised in every line, whereas now they excite interest only in a general way.

Again, the consumer would not only save money through economies in manipulation and design, but his material would actually cost less, due to the reduction in cost to the manufacturer, resulting from the production of a standard article. The small consumer, also, not having sufficient appliances for accurate testing, would be more sure of the character of his material. Under the present system he is liable to get all the inferior products of the mill and the shipments which have been condemned on more important work, whereas if only a standard grade of material were produced he would be more likely to secure a normal product.

Everyone connected with a laboratory for testing cement knows the great influence which details of seemingly minor importance exert upon the results. In the preceding part of this paper it has been assumed that uniformity in specifications is equivalent to uniformity in the material itself, but this evidently would not be the case unless the specifications were based upon a standard method of testing. For instance, one laboratory might obtain a certain value on a seven-day sand test and another might obtain a much greater value on exactly the same material. Therefore if the uniform specification called for a value intermediate between the two, the first laboratory would require a higher testing cement than the second, even should their requirements be identical. In order for a uniform specification, therefore, to have any practical value, it must be based on a standard method of testing.

The principal reason that tests of cement show such variations in the results obtained by different operators, is that it is one of the few materials that is not tested entirely in the form in which it is manufactured and sold. Bars of iron and steel, bricks and wood, are tested not only in the form in which they are to be used, but also in the form in which they are produced and sold. Cement, on the contrary, is made in one form, tested in a second and used in a third form.

The tests of cement may be divided into two classes: First, those which can be made with comparative accuracy, and second, those which are only relative owing to the great influence which the personal equation has upon the results.

The first class of tests are those made on the material as it is manufactured and sold, i.e. specific gravity, fineness and chemical analysis. The second class includes those tests which are made on the material after it has been subjected to certain processes and combined with other elements, and hence exists in a different form from that in which it was produced, i.e. time of setting, tensile and compressive strength and soundness

The first class of tests are capable of standardization, providing the apparatus and materials used are made and handled with precision. The second class, on the other hand, are subject not only to variations in the material itself, but also to variations in the other elements used with this material and to variations in the processes employed in combining them.

On account of the difficulty of procuring suitable apparatus for making tests and of manipulating it with exactness, variations will be found to some extent to affect all tests.

The determination of specific gravity is probably least subject to variations due to differences in method where reasonable care is exercised in its manipulation.

The test of fineness, on the other hand, is subject to variations on account of the difficulty of procuring standard sieves and of manipulating them with precision.

Chemical analyses are also subject to similar irregularities. In the tests made on pastes of cement, the inaccuracies of manipulation enter with double force, on account of the introduction of other elements and of the greater influence of the personal equation.

On account of these many possible sources of error, therefore, it is evident that every detail of manipulation and every piece of apparatus used must be prescribed exactly, thus standardizing the methods of testing if it is desired to adopt a uniform specification.

This, however, would not be the only advantage gained by the introduction of uniformity in methods. Even if there were no thought of adopting a standard specification, a standard method of testing would still be decidedly beneficial, in that it would place all results obtained on any material, in any place, on exactly the same basis. Under the present system the results of tests in one laboratory are of little practical value to another. If, however, these results all had the same basis they would have a direct bearing on, and be strictly comparable with, the results obtained elsewhere, which would vastly increase our knowledge of the behaviour of the material, and also render unnecessary a great amount of duplication of investigations.

For instance, a laboratory might make an apparently exhaustive series of tests investigating some property of cement. These tests might be repeated by a second laboratory, using different methods and probably obtaining results seemingly contradictory, thus leaving every one confused as to the indications of the tests, whereas if standard methods had been used the results would be much more likely to have been corroborative.

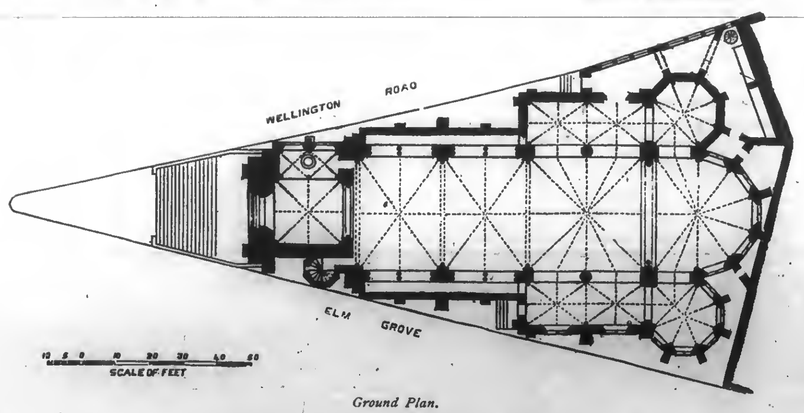
Standardization of methods, therefore, would have the great advantage of placing on a common basis all results either of routine work or of experimental investigations.

Another benefit also would be the doing away with the constant source of friction between manufacturer and consumer in regard to the results of tests. The manufacturer's laboratory may use a method giving high results, and the consumer's laboratory may yield lower values; both, however, being accurate as regards their respective method. The manufacturer, not always realising that the consumer's specifications are based on the results of his own laboratory, and not of the manufacturer's, is constantly endeavouring to show that the failure to meet the requirements is due to the consumer's methods. This is a comparatively unimportant matter, but it helps to show the many annoyances that could be obviated by standardisation.

The American Society of Civil Engineers, through the report of its committee in 1885, was the first to inaugurate a set of rules for the uniform testing of cement. While these rules served their purpose in an excellent manner for a number of years, they fail to entirely meet the requirements of to-day. This has resulted from several causes, among which may be mentioned, first, improved methods of manufacture; second, increased knowledge of testing and better acquaintance with the properties of cement; third, the demand for greater accuracy and the more rigorous requirements in specifications; fourth, the increasing importance and magnitude of the works of construction in which cement is used as the principal material.

In recognition of these facts, the Society has recently appointed a committee to report methods for the uniform tests of cement. In carrying out these instructions the committee is confronted with the difficulties attending the selection of standard methods by which uniform and comparable results may be obtained. Anyone engaged in the testing of cements must necessarily encounter the same difficulties and must realize that the basis of a standard specification is a system of testing which will give uniformity in results. This fact cannot be too strongly emphasised. It would therefore appear logical that the first efforts should be directed towards securing uniformity in methods of testing, then the foundation of a uniform specification would naturally follow.

*A paper read before the American Section of the International Association for Testing Materials by Mr. George S. Webster.



Ground Plan.

ST. JOSEPH'S CHURCH, BRIGHT N, ENGLAND.

A "FLAT-IRON" CHURCH.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—In an editorial last month (September) you made reference to the much advertised "flat iron" building recently erected on the corner of 5th Avenue and Broadway, New York. Many people imagine this building to be the only one of any importance ever erected on a similar gore. To show this to be a mistake, I enclose you herewith the plan and perspective of St. Joseph's Church, Brighton, England, built in 1879, on a gore similar to the flat-iron" gore. It will be seen the tower and steeple stand on the narrow end of the plot, and rise to a height of some 200 feet above street grade. This illustration is taken from the Builder of March 13th, 1880.

The church at the time came in for considerable criticism, because a perspective view of either side of the building obtained at certain angles, gave to the building a narrow and stilted appearance. Taken from the other end of the church gave it an appearance of being larger than it actually was.

F. T H.

Collingwood, Ont Sept. 8, 1902.

BUILDING STONE IN THE NORTHWEST.

Until recently the impression prevailed that there existed in the Canadian Northwest but little building stone. Investigation has revealed however that extensive deposits of more or less excellent quality, are to be found between Winnipeg and Lake Winnipeg extending as far west as Stonewall and east to Whitemouth Outcroppings are noticeable at Stonewall, Stony Mountain, Little Stony Mountain, Lower Fort Garry and East Selkirk. Stone from these points was used by the Selkirk settlers very soon after their coming to the country. Lower Fort Garry gives evidence of the use of this stone by the Hudson's Bay Company; the Kildonan church, and St. Andrew's church at the rapids are later examples. The early tombstones were made of the same material.

The Stonewall quarries have been considerably developed. Those at Stony Mountain have been used very largely for building in connection with the penitentiary. The main quarry at little Stony Mountain is owned by the city of Winnipeg and from it enormous quantities of stone have been used on the streets of the city, both as curb and foundation stone and for concrete and macadamizing. From the Selkirk quarry has come most of the ornamental stone used in Winnipeg.

Mr. Garson, formerly a contracter of St. Catharines, while erecting some buildings at Rat Portage, searched this territory for a stone which would meet his requirements, and located a deposit of 60 acres about two miles from Tyndall station on the C. P. R. and 29 miles from Winnipeg. He proceeded to develop the quarry and has already taken out 75000 tones of stone from an area of an acre and a half at a depth of less than 20 feet. As to the appearance of the stone, Mr. D. A. Dowling, B. A. Sc., in his report on the geology of the district says: "It presents a peculiar mottled appearance, which adds much to its beauty as an ornamental stone. This strange mixture of brown and white is difficult to account for. In some cases it appears as if its origin might be due to seaweed remains. Often the colo re portion approaches the color of yellow ochre and seems impregnated with iron, while the intervening spaces are more or less colored. So marked is this mottled condition that stone from this section can be distinguished at once from other stone in the Lake Winnipeg district."

The death is announced of George Farquhar, a prominent contractor of Toronto.

PUBLICATIONS.

Modern Carpentry — a Practical Manual — by Fred T. Hodgson, Architect; Frederick J. Drake & Co., Chicago, publishers.

This new work, by a well known author, consists of 195 pages enclosed within cloth covers, and copiously illustrated. It treats in plainly understood language of carpenter's geometry and joiner's work, and gives many practical examples of best methods of performing various kinds of work. The book concludes with a number of useful tables and memoranda for builders.

The London Builders' Journal tells of a contractor who has carried sleight-of-hand (on a large scale) into the domain of building construction. He was recently building a dozen houses, each with a kind of underground kitchen which the local authorities required to be connected with the rooms above by a staircase. Now a dozen staircases are expensive, and it occurred to this enterprising contractor that it would be much more economical to have one only. So he bought a substantial staircase and fitted it up to the first house, got the local inspector to examine it, and obtained his certificate. The staircase was then removed to the second house, where another inspection took place, followed by another certificate, and so on through the whole twelve houses. In the last house the staircase was allowed to remain, but—verb. sap.—in the others its place was taken by a step-ladder.

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

The Canadian Coral Marble Company has been incorporated, with head office at Toronto, and authorized capital of $500,000. The provisional directors are: S. M. Brookfield and H. J. Crowe, Halifax; E. D. Davison, Bridgewater, N. S.; J. W. Hutt, Liverpool, N.S.; H. W. Bickell, C.R.S. Dinnick and J. W. Moyes, Toronto, and T. M. Kirkwood, Owen Sound. The company is empowered to manufacture a composition known as coral marble for flooring, etc.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

LEGAL.

The City Solicitor of Toronto has given it as his opinion that when once a building permit has been issued the civic authorities have not power to revoke it. This opinion is the outcome of a petition by the residents of a certain district in the city of Toronto to have the same included in the brick limit, and pending the change to withhold authority from the holder of a building permit for a row of rough-cast houses.

It is satisfactory to learn, says the London Engineering Times, that the (British) Court of Appeal has confirmed the judgment already given that a building owner is responsible for the payment of provisional sums for work performed by special artists or tradesmen, or for other works or fittings to the building whenever the architect shall so direct. Building owners sometimes imagine that when a tender is accepted they have no liabilities except to the contractor, and in such cases it is difficult to explain to them that there are sub-contractors who have also claims, the payment of which does not necessarily increase the total amount they had undertaken to pay. In the case in question, Hobbs v. Turner, the contract form of the Institute of British Architects was employed. Clause 28, relating to the payment of provisional sums, was therefore accepted by both parties. It was mentioned in the specification that railings of the value of £20, exclusive of carriage, fixing and profit, were to be provided for, and they were supplied by the plaintiff. A certificate certifying that plaintiff was entitled to £27 10s was sent to the defendant, the building owner, by the architect. The defendant declined to pay, repudiating his liability, and alleging that he had a claim against the builder for bad work. The Master of the Rolls interpreted clause 28 as meaning that the building owner and not the builder should be considered as the principal in regard to it. In such matters the builder was only the agent of the building owner. But his Lordship declined to decide whether under clause 28 the architect had authority to determine who was to pay, as well as to whom payment should be made. Apparently it was the intention of those who drew up the form of contract that the architect was to have the power of choice, for the sums are to be paid at such times and in such amounts as the architect shall direct, and sums so expended shall be payable by the contractor or by the employer. The only directing power is the architect and it is not suggested that it is optional on the part of the employer to pay or decline to pay. It is to be regretted that the Court was not more decisive in dealing with this part of the question, although it may hereafter be accepted that the initial liability in respect of this class of work was established.

Showy Bathrooms TRADE MARK. J.M.T

are always features of the most finished houses.

Unattractive and unsanitary bathroom appliances destroy the pleasures of a bath as surely as muddy water.

Our bath room equipments supply all that can be desired in the make-up of an ideal lavatory.

Our line is one of many styles and shapes; of varied materials and combinations, of wise and sanitary constructions and of diversified prices.

No bath room should be equipped without thorough consideration of our offerings, information concerning which will be cheerfully sent on request.

STRUCTURAL WORK IN AMERICA.

In the course of a very interesting series of papers on structural costs recently published in the Engineer, the practice in tall building construction in America is set forth in a manner which shows clearly how economy is attained by keeping down the labor costs, says the Engineering Magazine.

The framework is so designed that the metal shall be handled the least number of times in the making. Planing is generally conspicuous by its absence, rolled or sheared edges taking its place. Rivets are so disposed that power driving can be used to the best advantage. Joints are so arranged that they require the minimum of work on site, and their rivets can be readily put in by pneumatic tools. Hand work is seldom to be detected—everything is as the machine has left it; as many girders, stanchions, beams, etc., are duplicated as is possible; stanchions are throughout spaced regularly; girder riveting is made alike in like spans—plates being added or dropped off as required for strength, thus one girder web plate template will often answer throughout the building; cast iron bases, pockets, shoes, and connection, where used, are just as the fettler or the tumbling barrel has left them; holes are cored or punched according to material; everything, in fact, is made most evidently for work and not for show. When first seen one is tempted to think off-hand that there seems much waste of material in places and much skimping of it in others. Brackets seem large and unwieldy, whilst cleats seem small and insufficient; girder flanges appear light, and stanchions ruggedly gigantic, or vice versa, according to the object of the building. But one has only to study things out a little to realize that all this is of set purpose. We are so used at home to providing against so many chances that are never likely to happen concurrently, that our structures have taken a character of their own, and we miss these characteristics when viewing other work. If workmanship can be saved by a slight sacrifice of material, the American carefully considers it. In no land are scientific principles better understood than in his, but he is much keener after the dollar than to sacrifice it for the sake of theory, and he will unerringly fix on the cheaper way of carrying out his principle. He keeps as far way from the smith's fire as he can, and does not enlarge his scrap heap with useless croppings and clippings, and as a direct consequence gets work made very much quicker, on the whole much cheaper, and quite as good and sound and equal to what is demanded of it as though it had been made to a government specification and was finished all over.

It may be argued that this sort of thing is not compatible with good work, but there is no reason why it should not be so. In masonry structures there is no attempt made to dress the inner faces of stone which is to be backed by rubble or brickwork, and since the structural work of a modern steel building is entirely imbedded it should be made to fulfill only those demands which legitimately come upon it.

Toronto Building By-laws.

IT is gratifying to learn that at last, presumably as a result of the loss of several firemen's lives by falling walls at the recent fire in a warehouse on Front street, action has been taken towards putting the building by-laws of Toronto in a more satisfactory condition. The Council have appointed Mr. A. F. Wickson, an ex-President of the Ontario Association of Architects, the City Commissioner and the Chief of the Fire Department, to revise the by-laws and recommend necessary amendments thereto. These gentlemen should and no doubt do know what changes are required to bring the by-laws up-to-date. They are now so far behind the times, that their proper amendment will involve considerable research and labor on the part of the Commission. We trust however that the subject will receive at their hands the attention which its importance demands, and above all that the Council will lose no time in adopting their recommendations and having the same printed in convenient form for the use of architects, builders and the citizens generally.

Fixing the Responsibility of Labor Unions.

THE fact is coming to be generally recognized that Labor Unions should be held responsible for losses sustained by employers by reason of interference by the Unions with their workmen, or the boycotting of their goods. A case in point is that of the Metallic Roofing Company, of Toronto. Because of a difficulty which recently arose between this Company and their employees, the Tinsmiths' Union have organized a boycott of their goods. The company have brought an action for damages in the courts against members of the Union individually, as well as against the Union collectively, with the object of finding out to what extent they can legally be held responsible. The result of this action will be watched with much interest by employers. If it should be decided that there is no legal redress to be obtained against the Unions or their members, then application will no doubt be made to Parliament to enact legislation under which labor organizations could be held responsible and liable for any damage or loss which their actions might entail. Meanwhile an organization of employers in all lines for defensive purposes has been formed.

Establishing a Building Site in Law.

A MOST remarkable case involving the legality of a building site, has just been adjudicated on at Gore Bay, Ont. Action was brought by the ratepayers of school section 2 of the Township of Allan to secure a declaration of the courts establishing the legal school site of the section upon a certain lot, known as "the old site."

The defendants were two of the school trustees sued personally and the Public School Board of the section, who maintained the legal site to be on a different lot known as the "old site." The trouble began as far back as December, 1899, when the ratepayers decided a new school should be built. The school board met and selected, subject to the approval of the ratepayers, the "new site." Then the ratepayers met again, and it is said approved of the new site, although the minutes of the meeting did not show that anything was done. The court on the strength of parole evidence affirmed that the ratepayers had approved of the "new site." This gave rise to dissention, and the dissentients appealed under the statute to the school inspector, who called another meeting of the ratepayers, at which the "old site" was chosen, and an arbitrator selected to act with the inspector. These published an award in favor of the "old site." While these proceedings were going on the Board of Trustees purchased the "new site," erected thereon a school building, and moved into it the school furniture. A motion to restrain them was refused. The courts also declared the inspector's action illegal. At the election of trustees in December, 1900, however, the advocates of the "old site" found themselves in the majority on the Board, and at once removed the school furniture back to the old building, whereupon three ratepayers applied for a mandamus to compel its return to the new building. Both parties then agreed to abide by the decision of the local judge, who declared the "new site" to be the legal site. The trustees acquiesced for the time in the view taken by the local judge, and returned the furniture to the new building, where the school was carried on until the summer of 1901. In April, 1901, however, at a duly convened meeting of trustees, a resolution was passed that the "old site" be selected as the school site for the section, and that a meeting of ratepayers be held on the 20th April to consider such selection. This meeting was held and the "old site" was adopted by a majority of seven. The court held as to this meeting that although the school site had been fixed by the action of the trustees and ratepayers in March, 1900, and a building erected on the site so fixed, it was competent for the ratepayers a year later to revert to the former site. In accordance with this view the action was dismissed and the costs declared against the plaintiffs. Nothing is said as to who must pay for the new school building, but presumably the School Board is the responsible party. In that case the new building will probably be allowed to remain idle, while the children are housed in the old one which several years ago was declared by the Board to be out of date. Such are some of the results of human perversity and legal wisdom.

Some Possible Results of the Coal Famine.

THE great struggle which is now going on between the owners and miners of the anthracite coal mines of Pennsylvania has resulted in placing the people of Canada and the United States in a very serious position. The inconvenience and discomfort which will be felt by all classes during the coming winter, should turn the attention of inventors and manufacturers to the necessity for heating apparatus in which fuel, other than coal, can economically be used. Unfortunately, central Canada, which contains the bulk of our population, has, so far as known, no coal deposits. Our coal mines are situated at the extreme ends of the Dominion—in Nova Scotia and British Columbia. The freights from these mines to central Ontario are prohibitive, so that we are obliged to depend for our supply on the United States. Wood has become too valuable a commodity in this country to be employed for fuel, except in country districts. Manufacturers of heating furnaces in Nova Scotia are adapting their apparatus to the use of soft coal, which fuel will no doubt come into general use to a much larger extent than formerly in the Maritime Provinces. In Ontario something else must be employed. The question suggests itself—why not petroleum or gas? Petroleum has long been used successfully on railway locomotives in Russia, and more recently, it is said, on railways in California, as well as on steamships, while in cities gas is already employed for cooking purposes. The designing of heating apparatus in which these kinds of fuel could be employed would seem not to be impossible, and we hope that the present situation will direct the energies of inventors to the problem. There is of course the further question of cost of fuel. Considering how large a percentage of coal is wasted, it would appear that either petroleum or gas might be supplied for the purpose at a reasonable cost. Heating by means of electricity would be an ideal method, provided the cost could be kept within reasonable limits. Thus far, however, it has not been possible for the electrical companies to supply at a reasonable price the necessary current and apparatus. Most of the central stations are operated by steam power, so that the cost is to a large extent based on the price of coal. In the United States central steam heating stations have been established in many towns. By this system steam is carried in underground conduits from central stations. This plan would seem to be better adapted for use in the business districts of cities than in residential districts. Steam, while undoubtedly the best heating agent for large buildings, is not as well adapted to house heating as hot water. A central heating plant was established at London, Ont., some twenty years ago, but proved unsuccessful and was abandoned. We observe that a Company in Montreal has announced its intention to establish a central heating station. Two or three years ago a number of companies were formed in different parts of Ontario to manufacture peat fuel, but the product has never been placed on the market, and some of the companies have abandoned the business. The difficulty in manufacturing this product is said to be found in connection with the drying of the material, after it has possed through the compressors. Natural drying is said to be necessary, in order to retain the most valuable constituents of the fuel, and this requires so much storage capacity and so long a period of time as to render the process unprofitable. We observe the announcement that a new process of drying is to be adopted by a Canadian company recently organized. This question is one of vital interest and importance in a climate like that of Canada and the United States, and we have confidence that in the near future methods of heating will be found which, if not cheaper, will be more cleanly and convenient than those which we have been accustomed to employ in the past, and it is hoped they will also render us less dependent upon one source of supply.

A TIME SAVING DEVICE FOR CONTRACTORS AND ARCHITECTS.

The primitive system of tendering for builders' work, which still obtains in this country; a system by which every man takes off the quantities for his own trade himself; has nothing that an ordinary person can see to recommend it except this one thing, that, if there is any mistake, the contractor has no one to blame but himself. The question is whether this advantage is an advantage; and, if so, whether it is an advantage sufficient to make up for the labour expended in taking off the quantities of innumerable jobs that he does not get.

It is quite possible for a contractor, who has not enough work, to take off the quantities of sixty or seventy buildings, in the course of a season. When one comes to think what this means for the principal trades, with the multiplicity of detail that has to be considered in connection with them, it becomes clear that there is in the system a great loss of labor to the community. A hundred men are occupied in doing the work which one could do, and do much better.

In the meantime while the contractors are playing at being quantity surveyors, their work is calling for them on the buildings upon which they are already engaged. Their current work is of necessity done without the care it ought to have. There is no time to really think about it. If the contractor can keep his contracts moving enough to keep the architect off his back, that is all he can do; and he cannot usually do this. There is no time for precision of work; for that love of seeing things done properly, which is bound to grow upon a workman who understands his work, and has time to think about it: and there is no doubt but that the standard of good work has been very much lowered for this reason.

It is left to the architect to oversee both the running of the work and its execution, neither of which matters are part of his function at all. An architect's function is to design buildings and see that the designs are carried out. If he, on his side, is conscientious about his work, and the circumstances demand it, of course this all comprehensive function has to be made to comprehend indefinitely. If a carpenter thinks a wire nail is as good as a tenon, the architect has to uphold the other doctrine. If the flooring has not made its appearance when flooring is due, the architect has to see that it arrives, and that it knows enough to come in out of the rain when it does arrive. But these are not properly parts of the architect's function at all. When an architect has supplied drawings for his design, and defined the quality of work required, it properly remains for him only to see that his drawings are understood. That he should have to see that the ordinary methods of good building are followed, or mingle himself with the contractor's business in order to have the work done with proper expedition, is in reality a disgraceful state of affairs; and it does not say much for "the dignity of labour" that contractors should be content with it. As long as contractors have not time to attend to their work, and are obliged to go about in fear of the architect, as naughty boys in fear of a schoolmaster; as long as the architect's attention is distracted from his designing; the standard of work is bound to be lower than it ought to be: and building, though one of the arts of peace brings anything but peace to those engaged in it.

To establish a system of tendering, which will relieve contractors of undue labor in that direction, is not likely to be a cure-all for bad work; but it will remove a condition of distracted attention which produces slighted work, from men who would tend naturally to do good work if they could give their minds to it; and it is safe doctrine to assume that these are in the majority.

The way out of the difficulty is evidently to have quantities supplied by a firm of quantity surveyors. Then the contractor need spend no more time over the

drawings than would be necessary in order to understand the general character of the work and examine particular points.

It would pay the contractors, in view of the time saved to them, to purchase their quantities; but this is sometimes done by adding a percentage to the contract price.

The principal objection to the system, that is likely to be raised, is the possibility of inaccuracy on the part of the quantity surveyors. A builder thinks he can trust himself better than anyone else. That is true, no doubt, under ordinary circumstances. But we are talking now of scientific quantity surveying. A specialist is sure to leave far behind the individual efforts of contractors with their hasty methods of arriving at an estimate. Accuracy and only accuracy is what he is there for. He lives by accuracy, and is likely to attain to it with more certainty than anyone else, as his whole attention will be given to method in attaining to it.

A quantity surveyor's bill of quantities will read something like the accompanying example, taken from the bills of the new Parliament Buildings at Victoria, B.C.

There would be no occasion with bills of this kind for the wide variations that are sometimes seen in tenders, even for small amounts. Their use would probably be more profitable on the whole and certainly more straightforward for all concerned. There would be more certainty and less friction. Even if it cost the builders some trouble at first, to make such new analysis of cost as might be required to estimate in this detailed manner, it would save trouble in the end.

It would be a good thing if the Victoria government's plan, of publishing a volume of quantities, could be repeated in Ontario or Quebec, for the next important building that is erected, so that the system might have a trial.

WILL THE COAL FAMINE AFFECT HEATING METHODS?

In answer to this question addressed to a number of the leading Canadian manufacturers of heating appliances, the following opinions have been received:

BROCKVILLE, ONT., Oct. 8, 1902.

Gentlemen,—Replying to yours of the 6th inst., we beg to say that in our opinion the present coal famine being a temporary difficulty only, is not likely to have a permanent effect on the designing of heating apparatus in the future. There is no doubt that apparatus in which other fuel can be economically used can be produced and in fact have been produced already. There are at the present time in operation successful heaters using both gas and petroleum but the great bulk of the work is still done by the better known fuels of coal and wood, and we think the future will be as the past in this respect seeing that there is still a bountiful supply of both classes of fuel.

Yours truly,

THE JAMES SMART MFG. CO.

GUELPH, Oct. 8th, 1902.

DEAR SIRS,—Answering your kind letter of the 7th inst. I would state that I do not think that it will be possible to invent a heating apparatus that will work satisfactorily with petroleum or gas. These materials are too expensive and the fitting up of the burners so as to work satisfacterily has been found to be very expensive. I have been in the business along while and have followed up every invention and suggestion that has been made and have come to the conclusion that a furnace using coal is the most economical in every way. Boilers have to be so arranged in their construction that it is necessary to have direct contact with the flame to secure the best results, and with gas or other fuel to do this the distribution of burners would be too great and consequently very expensive.

Yours very truly,

JNO. M. TAYLOR,
President Taylor-Forbes Co. and A. R. Woodyatt & Co.

TORONTO, October 13th, 1902.

Gentlemen,—Replying to yours of October 6th, we would say that we regard the present coal strike as of such a temporary character as not to affect in any large way the styles of construction prevailing in centers close to the anthracite regions. Anthracite coal is admitted to be so much better than any other fuel that in our judgment it will be used very largely notwithstanding the present unpleasantness.

The difference between ordinary furnaces for hard and soft coal is not very great, the chief difference being in size. The soft coal furnace requires to be at least one size larger for the given amount of work.

The burning of petroleum in furnaces can be very successful apart from the noise, which we think will be against it as applied to dwelling house, hospitals, schools, offices, etc., where it would be objectionable. In some New England kitchens, petroleum has been in use successfully for a number of years, but even in a stove it is noisy and objectionable for that reasen.

Yours very truly,

EDWARD GURNEY.

LONDON, ONT., Oct. 7th, 1902.

In reply to your communication of the 6th, the present shortage of coal we conclude to be only of a temporary nature, and will only temperarily affect the process of heating as now conducted. There is an evolution going on in heating as well as in other lines, which will be regulated by the value of the fuel and the manufacturers will conform themselves accordingly. Up to the present there has been no more economical way of heating than by using anthracite coal, subsequently however the developments in the production of peat may be perfected to such an extent that it will make this fuel cheaper, and it is certainly cleaner; developments in that respect however have not been as rapid as might have been expected, but the present shortage of anthracite coal may have the effect of urging producers in this line to place this article on the market earlier than they otherwise would do. The supply of oil for fuel is so limited and of so uncertain a nature that unless new fields are developed, no improvements in this line are likely to be forthcoming.

We are at present manufacturing furnaces that will burn bituminous coal and coke equally well; the chief prejudice against bituminous coal being that it is not so clean to handle as anthracite.

THE MCCLARY MFG. CO.

MONTREAL, October 8th, 1902.

Dear Sirs:—In reply to your enquiry of the 6th inst., it is our opinion that there is no prospect at the present time of any other fuel or method of heating to supersede the use of Anthracite Coal for individual plants, private houses, etc.

The most economical method of heating is by hot water and anthracite coal can be more easily controlled and requires less care than any other fuel.

Most hot water boilers, especially large sizes, can burn soft coal to very good advantage, but more care has to be taken in firing, and more attention paid to keeping flues clean. Probably for large cities, central plant and heating by steam will be found more economical and more satisfactory to tenants.

It is possible also that non-illuminating gas can be made cheap enough to use in private houses for heating and cooking, but at the present time this does not seem practicable.

Reference is frequently made to the immense deposits of peat which are to be found all over Canada, but so far no process has been invented to expel the water from it, and fit same to burn, at a price that will compete with other fuels.

With regard to the use of petroleum, the supply of this is so limited and in so few hands that should there be any further extensive consumption of it, the price would be likely to rise in proportion. Therefore, for many years to come we must depend mainly upon anthracite coal for house heating, and no doubt when the present trouble is ever, it will be sufficiently low in price to be within the reach of all.

Yours very truly,

H. R. IVES & Co.

ARCHITECTURAL EDUCATION AT UNIVERSITY COLLEGE, LIVERPOOL.

There are two courses open to students:—(a) The three years' course leading to the degree of B.A., with Honours in Architecture. (b) The two years' course, at the end of which the college certificate is granted to successful students. These courses are arranged for students to take before entering an architect's office. They are not intended to supersede pupilage, but to be preparatory to it. The two years' course has been in existence for eight years; the degree scheme was only started last season. (University College, Liverpool, is the only college in England in which students can study for such a degree, although such courses exist in all the principal universities in America).

The leading architects of Liverpool have signified their hearty approval of the schemes, and have agreed to shorten the term of pupilage and reduce the ordinary premium for students who have been awarded the college certificate or have taken their degree. The two courses are framed to prevent the waste of time which invariably results when a student enters an office without any previous knowledge of drawing, building construction, and the elements of architectural design. Students entering in October will have the exceptional advantage of being able to follow, from commencement to finish, the erection of the new laboratories for physics and topical medicine which are being built on college ground from designs by Messrs. Willink & Thicknesse and Professor Simpson. Candidates for the B.A. degree are required to pass:—(a) The preliminary examination of the university in five subjects: (1) English language and English history; (2) mathematics; (3) Latin; (4) elementary mechanics; (5) one of the following—Greek, German, French. (b) The intermediate examination for the ordinary B. A. degree is in the following subjects: (1) one of the following—Greek, Latin, French, German, Italian; (2) one of the following—ancient history, modern history, English literature; (3) one of the following—physics, pure mathematics, applied mathematics. Candidates are required to present certificates of having attended: (a) the approved classes for the subjects presented in the Intermediate examination; (b) courses of instruction in architecture and allied subjects averaging not less than five hours a week in the first year and fifteen hours a week in the second and third years. Such courses shall include all the subjects presented for examination. An attendance of not less than fifty hours in the department of engineering is required from all candidates.

The subjects of examination are:—(a) History of ancient and mediæval architecture; (b) history of modern architecture; (c) construction and planning of buildings, including sanitation; graphic statics; (d) architectural drawing. And any two of the following:—(e) Freehand drawing; (f) modelling; (g) decorative design; (h) applied mechanics; (i) art and theory of painting; (j) art and theory of sculpture. Students are strongly advised not to commence the three years' course until they have passed the Preliminary examination. Although it is possible for a student to be privately coached for the subjects of this examination during his first year, passing his Intermediate at the end of the second, such a course is not advisable, nor is it recommended.

The two years' course includes freehand and architectural drawing, construction and building materials, the history of ancient, mediæval and Renaissance architecture, perspective and sciography, graphic statics, engineering, &c.

Students who receive a first class certificate at the end of the course are specially exempted from the Intermediate examination of the Royal Institute of British Architects. This is the first college or institution in England to whom this privilege has been accorded.

OLD GOVERNMENT HOUSE, FREDERICTON, N. B.

LINEAR PERSPECTIVE.

At a recent meeting of the Association Section of the Edinburgh Architectural Association Mr. Robert F. Sherar, gave an interesting lecture on linear perspective illustrated by photography. After briefly tracing the history of the science from the conventional representations of the ancient Egyptians to the finished realism of the Middle Ages, he said that the researches in the science as such had been practically exhausted by Dr. Brook Taylor and successive writers in the eighteenth century; however, it was always possible to improve on the methods of stating facts and of teaching. The lecturer condemned the confusion of ideas expressed by the somewhat ambiguous term "picture-plane," and then discussed a few questions arising perennially from this confusion. Among these questions was that this he laid down the rule that the perspective appearance depended on the position of the spectator, and on this only; and that the perspective image depended on the surface on which it was delineated, whether it was a picture-plane vertical or otherwise, or a picture curved as a panorama, &c.

In dealing with the distance a spectator should be from the the object in order to produce an agreeable result, he showed three very interesting photographs of the east end of Prince Street with the Calton Hill in the distance, and said he had often heard it remarked that photography did not give correct perspective of distant hills, &c., as it always rendered them too small. The first photograph above referred to showed the Calton Hill about a quarter of the height of the buildings, the second showed it the same height, and the third showed

OFFICERS' SQUARE, FREDERICTON, N. B., SHOWING SOME OF THE MAGNIFICENT ELMS WHICH ADORN THE STREETS.

of vertical parallel lines converging towards a vanishing point as they receded from a spectator. Having proceeded so far in a critical manner, he then described the different uses and applications of the science as an aid to the architect or painter, and with the aid of photographs taken for the purpose he very lucidly described the elementary conditions on which the science depended and was distinguished between the perspective appearance of objects as seen and the perspective image as drawn on paper. He showed two photographs of the same building taken from the same spot which were quite different in the perspective lines, and explained that they were both equally correct records of the perspective appearance as we saw it, but records only. To prove this he then showed a photograph of the first of these two pictures taken with the camera placed in front of it, so that its image fell on the left-hand side of the photographic plate instead of the right-hand side, and the result was the same as the second picture. From it twice the height. This, he said, all depended on the distance the spectator or photographer was from the object to be represented, The choice of the distance was one of the most important preliminaries of picture-making, whether by photography or other means. He agreed with all the later writers on perspective that no rule could be laid down except in a general way in order to guide the artist, the conditions varying so much in each individual case. He laid great stress, however, on the fact that these conditions should be thoroughly understood, and said they were the very things that were not clearly defined in modern books on perspective.

It is announced that Mr. Louis Hebert, the Canadian sculptor, will soon return to Montreal to reside permanently.

Mr. S. G. Curry, architect, who at the last municipal elections was elected a member of the Toronto City Council, is doing excellent service. As an illustration may be cited his business-like resolution for an appropriation of $50,000 by the Council for the purchase of fuel to be so'd at cost to the citizens.

COMPETITION FOR McKINLEY MEMORIAL.

Charles J. Cohen, Secretary of Committee, 320 South Broad Street, Philadelphia, invites competitive designs until March 2nd, 1903, for a memorial to the late President McKinley. The memorial is to cost $30,000 and is to include a portrait statue with suitable accessory architectural features. Five premiums of $500 each are offered. The author of the successful design will be given the execution of the work, if in the Judgment of the Committee he be competent. The designs are to be shown by models to a scale of one and one-half inches to the foot. The jury of award is composed of Wilson Eyre, jun., Theophilus P. Chandler, Edward H. Coates, Charles E. Dana, J. Q. A. Ward, Paul Bartlett and Frank Miles Day.

BY THE WAY.

The rumor that an American Building Trust is to be formed with a capital of $66,000,000, to undertake the reconstruction of old London, has inspired the following from Punch:—

Say, are you sure that your Combine
(Or is it Combine?) will be grounded
In all the classes of design
With which we love to be surrounded?
Can you, for instance, emulate
Our Ludgate Bridge's gorgeous gilding,
Erect the Fleet Street Griffin's mate,
Or beat the Admiralty building?

Can you prepare us plans to rank
With British Art's supreme creations?
Could you have built the Birkbeck Bank,
Or Paddington and King's Cross Stations?
Will you, when decorating walls
(Like some with whom we're well acquainted),
Declare the frescoes in St. Paul's
Are not so bad as they are painted?

If so, we greet you—oh, but stay,
It's only right for us to mention
That others in the building way
Are giving us their best attention;
And so we fear you cannot come,
Unless the Trust that you announce 'll
Put by a fairly handsome sum
To pension off the County Council.

× × ×

The City Hall tower, which is the most prominent architectural feature of Toronto, has narrowly escaped destruction by lightning. An electric discharge struck the apex, destroying the terra cotta finial and tearing off a considerable quantity of the tiling. Mr. E. J. Lennox, the architect of the building is reported as having said that he does not approve of placing a lightning rod on the tower. The most direct way to ground would be down the face of the tower which would be a disfigurement. If carried to ground over the roof of the building the rod might prove a menace to the whole structure. An attempt to protect the building would probably require the placing of conductors at numerous points. There is an old adage, to the effect, that "lightning never strikes twice in the same place". If true, the City Hall may be now considered safe for the future. The subject of the protection of buildings from lightning is one on which there appears to be great lack of exact information. It would be interesting to know with certainty whether a tall building, or projecting features such as towers and spires, are more liable to lightning attack than dwellings and other buildings of ordinary height. The fact that the recently destroyed Campanile at Venice was on numerous occasions damaged by lightning is evidence in favor of the theory that height adds to the danger. It will be remembered that soon after its erection the top of the Washington Monument was damaged by lightning, whereupon it was surrounded by a number of lightning conductors and has since escaped attack. Whether or not its immunity is due to the protecting device is of course an open question. On the other hand the results of ordinary observation would seem to prove that height has nothing to do with the matter as apparently low structures are as frequently struck as high ones. It is no doubt true that a building may be protected by means of lightning conductors, if they are sufficient in number and properly constructed to carry off the discharge, but if not, they are but an additional source of danger.

THE CATHEDRAL AT FREDERICTON N.B.

This building, an illustration of which is given in the present number, is a conspicuous feature of the capital of New Brunswick. It occupies a trangular site of considerable size in the centre of the city, and is surrounded by some of the magnificent elms which adorn the streets.

The structure is entirely of stone with the exception of the spire, which is of wood, covered with metal. The architects were Messrs. Butterfield, of London and Wiles, of Exeter. The dimensions are length, 159 feet, breath across transepts, 70 feet, height of roof 62 feet, height of spire, 178 feet. In the tower are hung a chime of eight bells, weighing 2800 pounds, cast by Warner, of London.

The windows are of stained glass, chiefly by Wailes, of Newcastle-on-Tyne. Those in the north and south aisles, recently placed, are by Clayton & Ball. The pews are of butternut and the pulpit of oak. The many handsome gifts to the Cathedral include an elaborately carved stone font, a brass lectern, carpet of needlework, altar cloth, alms dishes, communion plate, and a Bible presented by King Edward on the occasion of his visit when Prince of Wales.

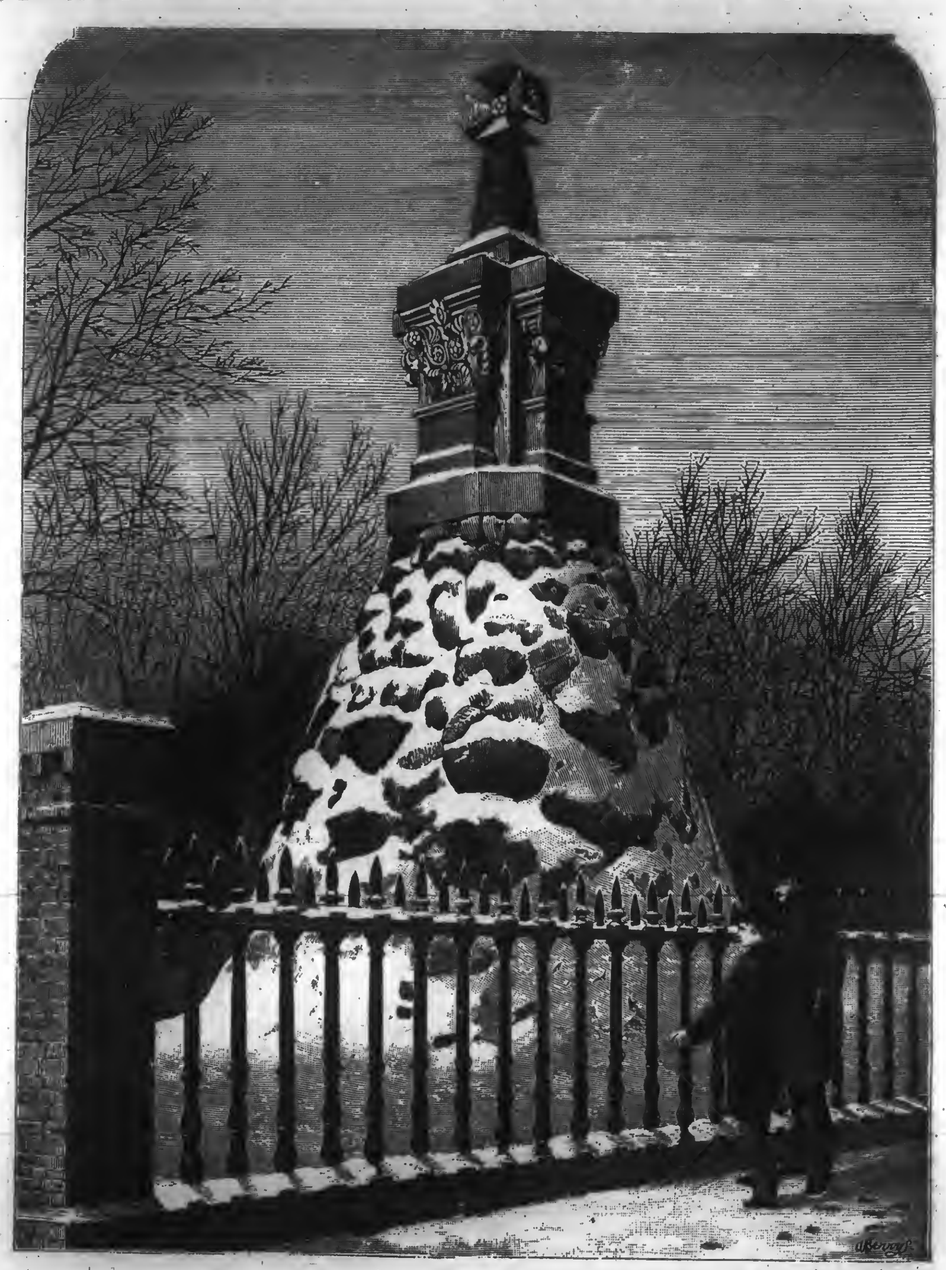
The Cathedral was begun in 1845 and completed in 1853, the founder being Bishop Medley, first Bishop of New Brunswick whose marble cenotaph occupies a place in the transept.

GREEK COLUMNS.

So far from employing pedestals to columns, which some have considered as forming as essential a part of an order as the entablature, the Greeks placed their columns immediately on the floor or uppermost step, the whole temple being generally raised on a low platform, to which the ascent was usually by three deep steps or gradini, serving as a base to the edifice; the depth of the steps was not accommodated to the human stature, but regulated so as to accord with the dimensions of the column. It is therefore conjectured that either a sloping platform of wood or lesser steps of the same material were employed as the real ascent to the temple. The Greeks invariably placed their columns singly, never in pairs, as has frequently been done by modern architects, and which, if not utterly indefensible, ought never to be resorted to unless required by positive necessity; for instance, where wider intercolumns than the scale of the order will properly admit are required; in which case, by affording additional support to the entablature, coupled columns not only excuse the width of the intervals, but take away the air of poverty that would result from single columns placed at the same distance from each other. Coupled columns are most of all offensive when forming a prostyle colonnade, especially if it be one with a pediment, since that disposition approximates so closely to that of the front of an ancient temple as to render any incongruity the more striking.

AN ARCHITECT'S TOMB.

The accompanying engraving represents the tomb of the late John G. Howard, architect, of Toronto, and his wife. It is situated in High Park (formerly Howard Park) in the western extremity of the city. This magnificent natural park of 160 acres was given by Mr. Howard to the city and will ever remain a memorial of his liberality and public spirit.



The late Mr. Howard was born in England, July 27th, 1803, and served as articled clerk for three years with Messrs. Ford and Paterson, architects and civil engineers, London. On Sept. 14th, 1832, he arrived in Toronto. In February, 1833, he won in competition the appointment of Drawing Master of Upper Canada, and held the position for 23 years.

Between 1834 and 1844 he was awarded premiums for plans submitted in competition for laying out the market block, Toronto, for gaols and court houses at Toronto, and London, Ont., for market and Queen's College, Kingston, Ont., and for Provincial Lunatic Asylum, Toronto. The latter building was erected under his superintendence in 1856.

For a number of years Mr. Howard occupied the position of City Surveyor. He was also a member of the Committee of Management of the first Artists' Society formed in Toronto, in 1834.

The following description of his tomb is reproduced from the London Builder of October 16th, 1880 :— The cairn is constructed with granite boulders. Mrs. Howard was a Scotch lady, which accounts for the cairn. Mr. Howard himself "is a Masonic Knight Templar.—therefore the double pedestal, terminating with the Maltese cross." The consecrated ground on which it stands is inclosed with some of the old iron railing which surrounded St. Paul's Cathedral, London, England, for 160 years. The cost of erecting the tomb, including vault and iron railing, amounted to $3,120. The granite boulders are all bedded in Portland cement against a brick shaft in the centre, which supports the marble pedestal. This weighs over 10 tons, and came from the Rutland Quarries, Vermont, U. S. Engraved on a brass plate, and fixed round one of the gateposts of the old iron railing, is the following inscription :—"Sacred to the memory of John George Howard and Jemima Frances, his wife. John George, born 27th July, 1803 ; Jemima Frances, born 18th August, 1802, died 1st September, 1877. Aged 75 years." On a brass plate fixed round the other iron gate post :—

"St. Paul's Cathedral for 160 years I did inclose.
Oh ! stranger, look with reverence.
Man ! man ! unstable man !
It was thou who caused the severance.
J. G. H.
Nov. 18th. 1875."

The vicissitudes of the railing are curious. After its removal from St. Paul's it was purchased by Mr. Robert Mountcastle, Waverlyplace, St. John's-wood, London, of Mr. J. B. Hogarth, iron merchant, London, and shipped by him in good condition, on board the steamship Delta, for Toronto, on the 14th of October, 1874. The Delta went on shore about five miles below Cape Chat Light, on the 8th of November. A portion of the railing was recovered from the wreck, and sent to Montreal by the salvage men in the spring of 1875, in a very mutilated state, but was brought from Montreal by Mr. Howard, 17th of August, in that year, and arrived in Toronto on the 21st of the same month. It was repaired by Messrs. William Hamilton & Son, at the St. Lawrence Foundry, Toronto, and finally fixed on the stone curb where it now stands, on the 18th of November, 1875.

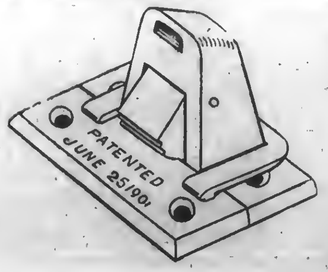
Adams' Automatic Self-Locking Sash Lock



The Adams Automatic Sash Lock is the only self-locking sash lock; is scientifically constructed; can be used on any window and put on by any person. It draws the sash together, thus keeping out dust, cold, etc., and prevents rattling.

P. S.—We have also patented a new **MORTISE LOCK**, which for neatness, durability and cheapness, should tend to revolutionize door locks. We will be pleased to send samples and quotations.

CORRESPONDENCE

A LEGAL POINT.

To the Editor of THE ARCHITECT AND BUILDER:

A. J. B., Woodstock, Ont., writes: Last spring I gave the contract to build a house, the contractor for the carpentry work signing an agreement to do the work according to plans and specifications, he finding all materials except hardware. The job is now nearly completed, but the carpenter refuses to put in the cistern which is clearly shown on the plans and marked "cistern," but is not mentioned in the specifications except in the excavations. Can I compel him to put in the cistern? If so can I order one put in and stop payment from contract on his refusing again to put it in? By answering this you will greatly oblige.

ANSWER: It is a difficult question that is asked, with the slender data given; the writer does not say whether the house is of brick, stone or wood. If of brick or stone, the cistern, which we understand is in the ground, and either stoned or bricked up, then it is clearly the mason's duty to make the cistern. If the building is of wood, then there is a doubt that can only be cleared up by a close reading of specifications and agreement. If the carpenter agreed to do all work mentioned or shown on plans and specifications, then he must make the cistern. One thing is certain, the owner cannot order the cistern to be made by a third party and deduct cost from contractor. If, however, there is a doubt, the owner may refuse to pay up the contractor until the work is finished, which will throw the onnus of entering an action on the contractor. Another and a better way, would be to have the architect settle the matter, if owner and contractor will agree to this method.

The London Builders' Merchant reproduces from the June number of this journal the illustration of interior of St. Annes des Plaines Church, Que. Of the CANADIAN ARCHITECT AND BUILDER, our British contemporary is kind enough to say:—"The journal is in every way of the highest class, beautifully printed on good hot-pressed paper, while the reading matter is well written by experts in the various subjects. The illustrations are also good, and include some excellent photogravures on separate sheets, in addition to photo-blocks in the text. The illustration which we give will show to our exporting readers that as the most artistic work is expected in Canada, so similar materials are necessarily in demand."

At the County Court, Westminster, on December 17, a plaintiff referred to a debtor as a man "with twenty trades, your honour," and produced his billhead to prove it. His Honour, looking at the billhead, said: "Is this what you mean—builder, decorator, paperhanger, gasfitter,' and so on?" "Yes, your Honour," replied the plaintiff. "Well, that's only one trade," said the judge. "I thought you meant he was a Jack-of-all-trades."—Plumbers' Review.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

BUILDING PROGRESS IN THE NORTHWEST.

WINNIPEG, Oct. 6th, 1902.

To the Editor of the CANADIAN ARCHITECT & BUILDER.

SIR,—With your permission I will run briefly over the building operations both Architectural and Engineering that have come under my notice since I arrived in the City some six months ago.

In Architecture little can be said from an aesthetic point of view, as the artistic side, owing to the conditions that govern all new cities, is still inchoate, and criticism in this direction must be touched upon very judiciously. Constructionally, work is good as is exhibited in the warehouses, etc., that have been built during the past two or three years. Previous to this time the importance of good foundations was overlooked and there are very few buildings that can boast of no cracks. The settlement in most of this work is caused by a substratum of very spongy-clay—something of the nature of a quicksand—about 6" thick and found at a depth of anywhere between ten and fifteen feet below the surface. Up to quite recently the practice has been, generally speaking, to disregard this altogether. Below this stratum a good hard clay is obtained which extends down to any necessary depth.

Apropos of clay, I think I might say a word about it, regarding the local brick. Whether it is the quality of the clay or the fault of the burning I do not know, but the "kiln run" that is generally used is a very inferior brick. Unless extreme measures are taken and a great percentage of what is delivered, rejected, very poor work is obtained. Also, as all local brick is of a yellowish gray color, a very hard, cold looking building is the result, and no soft effects can be secured, which are so helpful to many designs, especially in domestic work, when the red brick is used. A red brick is manufactured at Lac du Bonnett and Rat Portage, but the former is extremely soft and useless for good work, while the latter is just a trifle better. In stone, the same remarks regarding the cold hard effect of the brick may be applied to the local material (Tyndal). It is a hard grey limestone with iron colored streaks occasionally showing. It is a splendid stone to use where construction is the primary object, but not satisfactory for carving or fine or monumental work. It is being used extensively this year and the stone from some quarries shows considerable improvement on what has been used previously.

The season opened up so late this year that few buildings are in such an advanced stage as to allow of criticism touching design. The most important block, and the only one that can be said to be anyway in course of completion is the Merchants' Bank office building, (A. T. Taylor, F.R.I.B.A., Architect, Montreal.) This will be ready for occupancy persumably, about the end of the month, although the Bank are in possession now. This is a seven storey building and stands out very prominently as a modern office building and might almost be termed a "sky scraper" if comparison with surrounding work was to be considered. It is built of red pressed (Milton) brick and Bedford stone, the effect of which is at once bright and harmonious and the workmanship throughout is of the first order. A colonnade is formed above the height of the two top floors, with engaged columns supporting a copper entablature. The total depth of this is I think a little too great for the tout ensemble, but otherwise the exterior is generally pleasing. I enclose a photograph by which you may notice the points I have mentioned. The plan, generally speaking, is that of a good office building with two elevators. The ground floor is occupied, principally, by the Bank. In the Banking room proper an elaborately ribbed elliptical ceiling is used, which is very affective, but it is perhaps just a trifle overcrowded. The finish of the wood work in the fittings is excellent and challenges the work of any outside firm.

Of the other work in progress the Strathcona Apartment Block (Geo. Brown, Architect) in perhaps the largest. It has a foundation to about ten feet above the ground level of Tyndal stone and over this grey brick. This building is on the site of a foundation that was laid for an Hotel some twenty years ago, but the work owing to the boom and other reasons never advanced above the level of the ground, and it remained there till this spring. This building will be ready for the roof very shortly.

The Canada Life Assurance Company are having extensive alterations made to their premises, and in fact, as the work proceeds, it is hard to understand why any of the old building was left standing at all. The only portion remaining intact is the wall on Main street and Portage avenue, from the level of the first floor joists to the top of the second floor windows. The whole of the ground floor wall is to be taken out. Two stories are added to the old work, and with an extra thirty feet to the south a large five storey building will be ready for occupancy about the 1st January.

St. Stephen's Church, Portage Ave., which is being entirely built of Tyndal stone is well under way, also St. Mary's Academy which covers a large area, and when completed may be considered a great addition to the educational buildings of the city. The number of small houses in course of construction in the suburbs is astonishing, but the better class of residences is as yet very much in the minority.

Regarding engineering work, I think that very little is being

Glass as a Fire-Resistant.

A malleable glass is being manufactured at Matthews, Indiana, which is said to be capable of withstanding the greatest possible extremes of heat and cold, including sudden changes from the one to the other. In appearance this glass is said to be much like the ordinary product. It can be made of the thickness of a sheet of paper or as much heavier as desired. The material should prove valuable as ordinary window glass, but especially as a fire-resistant.

Insanitary Buildings.

IT is to be hoped that some definite result may follow the agitation now going on in Toronto to compel the removal of insanitary buildings. York street in that city will serve to illustrate conditions that ought not to be allowed to exist. For years this street, located in the very heart of the business district has been the abode of vice of every kind sheltered in tumble-down buildings, the owners of which reap large returns on their investments and profit largely by the improvements carried out by neighboring property owners. No doubt the local Board of Health has authority to order the removal of buildings which have become dangerous or insanitary. If so, we may hope that the Medical Health officer, who is known to be an energetic official, will now give his attention to the evil.

A Business Opportunity.

THERE would seem to be an opening in Canada for first-class furniture designer. As a result of the rapid increase of wealth in the last few years, there has come a demand for more costly residences and furnishings, and for specially designed furniture. Large orders for special furnishings have recently been given by Canadian architects to United States firms. Most of the furniture now manufactured in Canada is machine made from stock designs purchased in the United States. As a rule these designs have little or no merit, and are duplicated thousands of times so that they are everywhere in evidence. Persons who have the taste for something better and the means wherewith to buy, should in future have their requirements met by Canadian designers and manufacturers.

Esprit de Corps.

IF the profession of architecture is to be held in public respect and if associations of architects are to accomplish any useful purpose some of the members must be more particular than at present in their methods. Esprit de corps is not promoted by the knowledge that fellow architects have approached your clients and asked to be allowed to submit sketches free of cost, even after your plans have been approved and tenders thereon received. Conduct of this kind is unfortunately in evidence and

is one of the greatest stumbling blocks to the advancement of the profession. There cannot be good-fellowship among architects while petty jealousies and disloyalty prevail. Neither can clients whose attention is drawn to these things be expected to hold the profession in highest esteem.

Profitless Contracts. A Toronto contractor assures us that builders in that city are receiving very small profits from their undertakings. The times are prosperous and plenty of building is being done, but it is claimed that the keenness of competition and high prices of labor and materials are proving an off-set, and standing in the way of proper returns to the contractor. There are said to be about two-hundred building contractors in Toronto at the present time, which is far too large a number even in prosperous times like the present. Some of these men are so anxious to get a large amount of work that they tender at ridiculously low figures and thus lower the standard of prices all round. A much wiser course would be for all tenderers to allow in their estimates for a fair margin of profit, and thus assist in securing for builders their share of the results of the prevailing prosperity. If when the times are good little or no profit can be made, the outlook will be gloomy indeed when hard times shall return.

Smoke as an Explosive. A lecture was recently given by William McDevitt, Insurance Inspector, before the Fire Insurance Society of Philadelphia, in which the explosive quality of hot smoke was demonstrated. The author explained that in a fire, free carbon rises and mixes with hydrogen; methyl-alcohol, creosote and other gases are also present in smoke. These gases become heated to the point of ignition, and an explosion is the result. Of itself, smoke would explode at a temperature of from 600 to 800 degrees, but frequently the smoke is ignited by sparks or by coming into contact with a flame. Very thick smoke, when ignited, becomes a pillar of flame, and rolls through a room with such force as to shake the walls and make the windows rattle. If sprinkled with water there would be no explosion. Where formerly firemen tried to keep smoke in, under the impression that it smothered the fire, they now immediately break in windows or skylights to let it out. The construction of a central shaft in large stores and other buildings was recommended as one of the best methods of avoiding smoke explosions.

Sewage Disposal on Vessels. The beauty of the Muskoka Lakes and their value as a health resort have been published far and wide over the continent. As a consequence the number of persons who summer there is steadily increasing year by year. Dr. Bryce, the efficient head of the Provincial Health Department is keenly alive to the necessity of securing the adoption of such sanitary precautions as will maintain as nearly as possible the original purity of the air and water on these lakes. Most of the hotels, including the new Royal Muskoka, are fitted with the septic tank system of sewage disposal described by Dr. Bryce in his admirable paper read before the Ontario Association of Architects last year. Last summer the further step was taken of placing a septic tank on one of the Muskoka Navigation Company's steamers. The experiment is said to have proved entirely successful, all the sewage from the vessel with the exception of the liquids was consumed by the bacteria in the tank. It is probable that next year all the steamers on these lakes will be provided with septic tanks, thus stopping to a large extent the pollution of the water and greatly reducing the possibility of the spread of disease.

C. A. & B. STUDENTS' COMPETITION.

The publishers of the CANADIAN ARCHITECT AND BUILDER invite architectural students in Canada to submit designs in competition for a suburban or town house to cost not more than $2,500.

The building is to be designed for an inside lot having a frontage of 50 feet, situated on the west side of a street running north and south. The adjoining lots on either side have houses on them 30 feet back from the street line and 10 feet from lot line on either side.

Competitors are required to submit two elevations or a perspective, together with plans of basement, ground, first and attic stories, drawn to ⅛ scale in a manner to permit of reproduction within the limits of a double page of the CANADIAN ARCHITECT AND BUILDER, viz., 10x15 inches in size, also details to a larger scale of important or special features of the design. Drawings must be made with PEN and PERFECTLY BLACK INK on WHITE DRAWING PAPER, OR CARDBOARD. NO BRUSH WORK WILL BE ALLOWED.

Competitors should state the materials proposed to be employed in construction.

Drawings for this competition should be signed with a motto only and be accompanied by a sealed envelope bearing the same motto and enclosing the full name and address of the designer and the name and address of his principals. They should be sent FLAT by post or express, charge prepaid, addressed "CANADIAN ARCHITECT AND BUILDER, Toronto, Canada—Student's Competition," and must reach this office not later than noon on Saturday, January 10th, 1903.

The members of the joint Educational Committee of the Toronto Chapter of the Ontario Association of Architects and the Toronto Architectural Eighteen Club have kindly consented to judge the designs submitted in this competition, and their decision will be final.

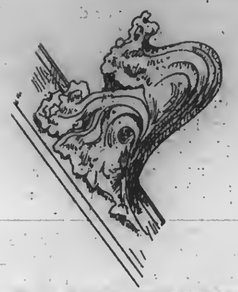
The prizes offered are: First prize, cash $15.00; second prize, cash $10.00, third prize one year's subscription to the CANADIAN ARCHITECT AND BUILDER ARCHITECTS' EDITION.

The publishers of the CANADIAN ARCHITECT AND BUILDER reserve the right to publish any of the designs submitted and to withhold the prizes if in the judgment of the jury the designs should not be found worthy of the awards.

Intending competitors are requested to read carefully the conditions of competition, and to strictly comply with the same in every particular.

Messrs. Ouellett & Levesque, architects, of Quebec, have registered a partnership.

A brilliant dark green for front gates or doors can be got by first and second coating on old work with two coats of Prussian blue and at least two of verdigris, to be finally finished with good, clear varnish, when the work, if properly done, will last for years, and cannot be successfully matched with any other greens on the market.



SCREEN, NORTH AISLE—AMIENS CATHEDRAL.

COUNT TOLSTOY ON ART.

Count Leo Tolstoy, in his book entitled "What is Art? makes a contribution to the question which can hardly fail to affect the progress of art in Europe.

Before making his own definition of art he gives a summary of the views of aestheticians for over 200 years, which must have cost him much labour. It is not easy reading and the conclusion he brings us to is that it is not profitable reading, because the object of the aestheticians is to discover the nature of art by the consideration of examples of all kinds — bad as well as good — and devising a definition of art to cover all these productions. The result of these investigations is a general conclusion on the part of the aestheticians that beauty is the object of art: "that art is that which makes beauty manifest, and beauty is that which pleases." Feeling the instability of this definition of beauty, "many aestheticians have asked themselves why a thing pleases," and "have converted the discussion on beauty into a question concerning taste," and there it squanders. There is no explanation of why a thing pleases one man and displeases another. So that the science of aesthetics fails as a science. "It does not define the qualities and laws of art, or of the beautiful (if that be the content of art), or the nature of taste (if taste decides the question of art and its merit), and then, on the basis of such definitions, acknowledge as art those productions which correspond to these laws and reject those that do not come under them."

Tolstoy quarrels with both the system and its result. He objects to the aim and purpose of art being considered to be the pleasure we get from it, as much as he would object to its being considered that the purpose and aim of food is the pleasure derived when consuming it. He proposes to define art first, and then decide what is and what is not good art by judging whether a work conforms or does not conform to the definition.

"In order to correctly define art," he says, "it is necessary, first of all, to cease to consider it as a means of pleasure, and to consider it as one of the conditions of human life. Viewed in this way we cannot fail to observe that art is one of the means of intercourse between man and man." The peculiarity of this means of intercourse he finds to be that whereas by means of words men transmit their thoughts, by means of art they transmit their feelings.

In order to be a true work of art the feelings transmitted must be the artist's own feelings, which he has lived through either in actual experience or by his imagination. It does not matter what the feelings are, whether they are strong or weak, bad or good: "feelings of love for native land, self-devotion and submission to fate or to God expressed in a drama, raptures of lovers described in a novel, feelings of voluptousness expressed in a picture, courage expressed in a triumphal march, merriment evoked by a dance, humour evoked by a funny story, the feeling of quietness transmitted by an evening landscape or by a lullaby, or the feeling of admiration evoked by a beautiful arabesque—it is all art."

He therefore makes the following definition:—"Art is a human activity, consisting in this, that one man consciously, by means of certain external signs, hands on to others feelings he has lived through, and that other people are infected by these feelings, and also experience them."

This is art—the definition seems indisputable—but it is not by any means the whole matter of the treatise. The author reaches this definition in 50 pages but there are nearly 200 beyond. He has still to mark off the classes of work which, though they have been usually considered to be art, do not conform to this definition, and to reject the classes of work which, though they do come under the definition and must be called art, cannot be upheld as serving any useful purpose.

The first of these two heads is of the greater immediate interest to architects.

In order the better to distinguish true art from false, Count Tolstoy traces the course of art from the early centuries of Christianity, when renunciation of the world was the motive of life, and art renounced the transmission of feelings of personal enjoyment; through the Middle Ages when, under the inspiration of the church, pious adoration, the fear of hell and the hope of heaven were the themes of good art; to the time of the Renaissance when the rich and powerful, no longer able to believe in Church religion and incapable of accepting true Christian teaching, stranded without any religious conception of life, involuntarily returned to that pagan view of things which places life's meaning in personal enjoyment. It is here he finds not only a great impoverishment of the subject matter of art but the source of the involved, affected and obscure art which has since grown up.

Art does seem at the time of the Renaissance to have fallen into a whirling gulf from which there is no advance, and the change of motive from religious feeling to pleasure would sufficiently account for it; for the satisfaction of pleasure brings merely satiation, while the satisfaction of religious feeling is a renewal of impulse.

In leaving the way of religious feeling and devoting itself to the satisfaction of easily staled enjoyment, art lost the greatness which belongs to it only when it is comprehensible to every one, and became an amusement of the upper classes; in consequence of which, in the pressure of meeting demands for art which did not spring spontaneously in the artists' inner self, artists have had to devise methods of producing imitations of art.

These methods are those of (1) borrowing, (2) imitating, (3) striking (effects), and (4) interesting.

"The first method consists in borrowing whole subjects, or merely separate features, from former works recognized by every one as good works of art and so re-shaping them with sundry additions that they should have an appearance of novelty." This method in its

adaptation to architecture, requires no comment. We are all familiar with it : indeed it seems as if whole fields of work in modern architecture are founded upon this method, and that a great part of modern architecture is a counterfeit art.

The second method (that of imitating) is shown in literature and the drama by dependence upon realism, in music by the attempt to imitate sounds, in painting by the photographic method. In architecture, imitation is too troublesome to be a temptation.

To imitate by architecture structures which are outside the field of architecture requires at least constructive invention. The temptation in architecture is to imitate itself ; to adapt to one branch forms which are only proper in another. It is this which gives us armouries that look like fortresses and which produced Wemmick's castellated cottage.

In the third method (striking) "the effects consist chiefly in contrast;" in bringing extremes together, and producing variations from the ordinary which strike by their unexpectedness. In painting Count Tolstoy describes the "chief and usual effects" to be "effects of light and depiction of the horrible." In architecture it is the creation of the horrible we have to guard against, and perhaps it is best done by applying the old rule for young writers that the part where one is conscious of effect is the part to score out : in other words not to try for effectiveness at all. Architecture consists not in effects but in idea : effects may strike but it is only the idea that infects.

The fourth method—that of interesting, that is too say of absorbing the mind with matter connected with the work—is the most plausible of all the counterfeits of art, for the interest does reside in the work and it is easy to mistake the excitement of interest for the transmission of feeling ; but as a matter of fact the occupation of the mind in this way rather hinders than assists artistic impression—or, to use a word which expresses Count Tolstoy's doctrine better, artistic infection. It is in this way that—to take an example from architecture—those residences which have a classic hall, a Jacobean dining room, a Gothic library, an English drawing room, and a Rococo boudoir fail to impress one with any feeling for the work as a whole, but to excite rather the somewhat wearying interest that one takes in a museum.

Art then is only real art when it infects the spectator (to confine ourselves now to architecture) with a feeling which is original with the artist. If it is original with the artist it must be new to the beholder, and Tolstoy says, "An art-product is only a genuine art-product when it brings a new feeling (however insignificant) into the current of human life." It is this effort after something new that has led designers to aim at what is striking or interesting. It is a mistake. The path to originality lies in renouncing originality. This is no great paradox when we come to see what it means.

Whoever heard complaints of monotony in the appearance of the human face? The poet may write "a sonnet to his mistress' eyebrow," fifty times and not repeat himself, if he only has fifty mistresses. No artist tries to improve upon the human nose when he paints a face. Ridiculous as the human nose is, its Creator has made it a beautiful object when its proportions are strictly suited to its needs. Striking effects do not improve it, nor do interesting embellishments. Why then should we hope to improve our own creatious by going outside of their functions for our inspiration? Why when we wish to procure the charm of freshness in our work in spite of the similarity of one problem to another, should we seek for any other inspiration than its functions, when we see how the human nose, with its similar functions and its similar form in all the multitudes of men, is nevertheless always new?

Here is Count Tolstoy's recipe for the production of infectious—that is to say of original—art. "The stronger the infection," he says "the better is art, as art, speaking now apart from the subject matter.

"(The fourth quarter of his book is devoted to the condemnation of much of the subject matter mentioned in the quotation from him, in the earlier part of this article, as being art. He considers no art to be good art which does not transmit either the feelings of religious perception or the simplest feelings of common life. And its function as one of the means of human intercouse is to unite men in feeling. Hence he excludes all art that transmits church or patriotic feeling or the feelings pertaining exclusively to the aristocratic and idle rich. These views however cannot be considered in the present article).

To return to the recipe for producing infection. Count Tolstoy says : "the degree of the infectiousness of art depends on three conditions.—(1) On the greater or lesser individuality of the feeling transmitted ; (2) on the greater or lesser clearness with which the feeling is transmitted ; (3) on the sincerity of the artist, i. e. on the greater or lesser force with which the artist himself feels the emotion he transmits."

Now these three conditions may, as the author himself says, be summed up in the last, sincerity ; for if the artist is sincere—as each man is different from everyone else, his feeling will be individual for everyone else ; and, if he be sincere, he will be sure to to be clear.

It is thus that renunciation of originality is the way to originality, for the designer must lose himself in his problem if he is sincere. And the encouragement to do so is that it is only when this imagination is thoroughly infected with his problem that he can express it so as to infect with his feeling those who look upon his work.

W. A. Langton.

ARCHITECTURAL MATTERS IN TORONTO.

The Toronto Chapter of the O.A.A. have decided to establish for the benefit of the members a class on the History of Architecture. The first meeting will be held in the O.A.A. rooms, 94 King Street, West, on the first Monday in December between the hours of 5 and 6 p.m. Under the direction of Mr. W. A. Langton the class will first take up the Norman period, and later the Early English period under the direction of Mr. John Gemmell.

A Committee composed of Messrs. Symons, Wickson and A. H. Gregg has been appointed to take charge of the scientific classes in connection with the educational work to be undertaken jointly with the Toronto Architectural Eighteen Club. Professional teachers will be employed for these classes, which will be of such a character as will prepare students for entrance to the School of Practical Science.

On the evening of the 11th inst. the members of the Toronto Chapter and of the Toronto Architectural Eighteen Club met in the rooms of the Association and discussed with Mr. A. F. Wickson the revision of the city building by-laws.

AN "ART NOUVEAU" HOUSE IN PARIS.

The Parisian who, starting from the Bois de Boulogne or from the Place de l'Etoile, walks along the Avenue Victor Hugo and turns into the Rue Saint-Didier, sees on his left an edifice of very novel aspect. In front, fenced off from the street by an ornamental railing of light construction, there is a court-yard, partly covered, and on the left of this court-yard a building of a character hard to define, but which gives one the idea of a chapel whose distinctive signs are hidden by details thoroughly modern in style. Behind the court-yard and chapel stands a spacious hall, the dome of which dominates all the rest. This hall is fitted up for concerts. Everyone who passes in front of the edifice asks himself: "Whatever can this be? What is this mixture of things so dissimilar—a court-yard, a chapel and a concert hall?" What it has been intended to build at No. 60, Rue Saint-Didier is an edifice of a special kind, comprising two things, namely, a public hall and a patronage. (A patronage is a sort of school where the children and young people who attend it are taught morality and religion.)

This edifice is called the "Ecole Humbert de Romans," after an ancient monk known by his writings on religious art, and particularly on sacred music. It is also a monk, the Pere Lavy, belonging to the Dominican order, who is the originator of this edifice. His idea was that it should be a school of divine art—a sort of religious and popular Conservatoire. Thanks to his great influence among wealthy people in Paris, the Pere Lavy succeeded in collecting about £40,000 for the erection of his academy. What interests us is the structure itself, the architect of which is M. Hector Guimard, who came into prominence as an exponent of the new architecture when he designed the stations of the Paris Metropolitan Railroad.

The edifice in the Rue Saint-Didier had to comprise a concert hall capable of holding from 1,500 to 2,000 persons. It had to have a gallery. On one side there was to be a stage, with a grand organ at the back of it. Besides the hall itself there were to be the necessary subsidiary buildings, such as the cloakrooms, lavatories, vestibules and so forth. The establishment also had to have a janitor's lodge, a chapel 27 metres long by 8 metres in width for the accommodation of the Pere Lavy, and a patronage communicating directly with the hall.

The principal facade, as already stated, is on the Rue Saint-Didier. In front of its central part, however, there is a fairly spacious court-yard, separated from the street by an ornamental iron railing 7ft. high. Entering by the doorway on the right, one first reaches an outer vestibule, in which there is a vestiary, fitted up in such a manner that the garments are hung upon pegs. Two other vestibules lead out of this first one, and the effect is that the hall has wide exits on three of its sides. These vestibules all have a floor in pink imitation marble with a pattern of lilies and golden nenuphars. They are built of stone, iron and cement, like all the lower part of the edifice, and thus are practically fireproof. They communicate with the hall by a continuous row of doors, which arrangement is very convenient and constitutes, moreover, a safeguard in case of fire.

The hall is 29 yds. long and 25 yds. wide. It is formed of a visible structure, springing from the ground at each corner and spreading in curves like the branches of an immense tree, in a way which gives one some what the idea of a corner of a Druidic forest. The main branches, eight in number, support a rather high cupola, pierced, like the sides, with bays filled with pale yellow stained-glass, through which an abundance of light finds its way into the hall. The framework is of steel, but the metal is covered with mahogany in all visible places. What is in reality a thin strip of steel thus has the appearance of a thick beam. The pillars, for example, measure as much as 20 in. by 15 in. at the foot and 11½ in. at the top. The principal rafters also measure 11½ in. each way, and the principal tie-beams begin with 15½ in. and finish with 10 in. on each face. Nevertheless, the tie-beam being 35 ft. long has a light and elegant appearance, owing to the great distance between the supporting points. Three hundred cubic meters of mahogany were used for the framework, and the result is the most elaborate roof ever conceived by a French architect. The mahogany is polished, has a warm red colour, and stands out from voussoirs of the ceiling, which are painted orange colour, shaded gradually lighter in the direction of the spectators. These voussoirs, between the rafters, are in plaster, decorated with antique masks and with trumpeters in the corners. A part of the ornamentation has been done in sheet-iron and forged iron platbands. To the arched buttresses electric lamps are fixed in groups of twelve, having the appearance of branches of strange fruit on foliations of iron.

At the bottom of the hall there is a platform or stage, and a fine organ with forty-four stops, built by Abbey. The case of the instrument is of mahogany, in the same style as the hall. The stage is large enough to hold 100 musicians and 120 choristers.

The hall contains 1,150 numbered seats, but there is so much unoccupied space that an audience of 1,500 or 1,600 could easily be accommodated. The armchairs are roomy, with plenty of space between each row, and they are placed quincunx-wise, in order that everybody may have a clear view of the stage. These chairs have a light cast-iron frame in the form of branches ; the seat is of green leather, stamped with curves and volutes. Two staircases lead to the upper floor, which is provided with armchairs similar to those in the hall below. On the left there is a spacious room suitable for use as a lobby or as a promenade. The balcony of this floor is in iron, and it is decorated, like the balustrades of the two staircases, with lyres and musical notes. The acoustic properties of the concert hall are excellent. It vibrates extremely well, and has no annoying echo. It is an ideal hall for stringed instruments and for the voice. It vibrates almost too much for brass instruments, which have to be moderated. M. Camille Saint-Saens gave some valuable hints in this connection, and it was upon his advise that M. Guimard, in order to obtain the requisite sonorousness, planned a proper distance between the ceiling and the roof of the hall, so that they should have a cushion of air between them.

The exterior of the edifice is built of free-stone, with certain parts in millstone, brick and iron. The carving, which is interesting here and there by reasons of its fanciful treatment, has been done from models composed by M. Guimard himself, who also designed all the ornamental tiles.—The Builders' Journal.

COMPETITIONS.

A prize of 3000 lire is offered by the municipality of Venice for the best design submitted for a large gold medal to be awarded to the most important works shown at the International Art Exhibition of 1903 to be held in that city. Competitors are required to submit wax or plaster models to the exact diameter of 120 mm., accompanied by photographic reproductions 40 mm. in diameter, which will be the size of the medal. These must reach, postpaid, the office of the Secretary of the Exhibition not later than the 31st of January next, and must be signed with a motto, and be accompanied by a sealed envelope containing the full name and address of the author. The committee of award consists of the Mayor of Venice, the President and Secretary of the Exhibition and three artists.

SCHOOL OF PRACTICAL SCIENCE; CHEMISTRY AND MINING BUILDING.

On concrete foundation walls now in place at the head of McCaul Street, Toronto, the Ontario government are proceeding to erect the brown stone and brick building shown in front elevation, in illustration plate, as it will appear from College street. The plan will cover about 262 feet from east to west, with two wings, of which the western will have a depth of about 130 feet and the eastern 102 feet. It will be placed about 30 feet back from the street line. This building is for the accommodation of the Departments of Chemistry and Mining of the School of Practical Science. Students in all departments of the school will thus attend this building for all lectures and laboratory work in Chemistry and Metallurgy, as well as the students in Chemistry and in Mining Engineering. The accommodation provided in this building will also be made to suffice for the classes in Mineralogy and Geology in the Faculty of Arts.

In addition to a sub-basement for pipes, there will be four floors available for purposes of instruction and research. A main corridor runs east and west on each floor, from which access is obtained to rooms on each side as well as to the two wings of the building. Ventilating fans will be provided in the basement which will deliver fresh air, screened from dust, and warmed if necessary by steam coils to 70 degrees Fahrenheit, to the different rooms; but in winter the main heating will be done by radiators distributed through the building and used as required. The air will also be exhausted by fans in the attic when it is desired to have better ventilation. In this manner the ventilation and heating in each part of the building are separately under control.

The steam coils and radiators while in use will be supplied wholly or partly from the exhaust steam of an engine driving a D. C. dynamo, from which the ventilating fan motors will be supplied, as well as the current for lighting the new and the old building. At other times the usual city service will be used.

The museums for minerals and geological specimens will occupy an area about 50x80 feet in the east wing. In addition to lecture theatres, chemical, mineralogical and assay laboratories, metallurgical furnaces, and work rooms for fossils and minerals, lithology and crystallography, there will be a number of rooms for special purposes, such as calorimetry, gas analysis, toxicology, photography, electrolytic assay, fire-proof and constant temperature rooms.

Next spring the Milling Building of one storey, about 75 feet square, will be begun on ground at present occupied by the old Wycliffe College building, immediately north of the centre of the new building. The Milling Building will be equipped with such appliances as are usual in modern milling laboratories, such as stamp mills, vanners, rolls, separators, leaching plant, etc.

CONDITION OF VENETIAN MONUMENTS.

The Commission for the Inspection of Venice Monuments has presented the following report:—

The Doge's Palace.—The Commission is not aware that anything new threatens its stability, but the weight of the books of the Marciana Library must be removed.

The Procuratie Vecchie.—In this building, which forms the north side of the Piazza of St. Mark, the whole of the internal arrangements have been altered to meet the needs of trade and commerce. Besides which tons on tons of goods, a large part of which consists of glass, are stored there. Consequently cracks have appeared, and though there is no danger of collapse, still work of restoration is urgently needed. Signor Boni said he should like to see the buildings turned into dwelling-houses, thus restoring them in great part to their original use.

The Campanile of S. Stefano.—The upper half of this campanile was rebuilt after the destruction caused by lightning in 1585, but it is precisely this part that now threatens to fall. It is nearly 6 feet out of plumb. Signor Boni has therefore ordered the demolition of the newer upper half.

The Campanile of S. Barnabas.—Near the base of this campanile cracks and bulgings have been discovered. The Commission have, therefore, ordered the cessation of the ringing of its bells and they contemplate immediate repairs.

The Campanile of San Francesco della Vigna.—The Commission finds that this campanile needs strengthening. Its bells, too, have been ordered to be quiet. Signor Boni says it may have been built too near the banks of some old canal.

The Bell Tower of the Arsenal, in which hung the modern "Marangona" that called the workers to their labours, has been condemned to undergo repairs. The bell has been swung to the top-mast of a ship, and meantime does duty there.

The Church of Mater Domini is dark, and low and dismal, and the Commission report it to be in a positively deplorable condition. It will have to be closed and thoroughly overhauled and restored.

The Church of the Maricoli, considered to be one of the most beautiful Renaissance churches in Italy, has been ordered to be closed so that the necessary work may be done to preserve it.

A controversy is going on in the eastern States as to the point at which building operations begin. On the one hand it is contended that the point of commencement is the excavation. Against this C.H. Blackall, a prominent Boston architect, states that in his own experience about 10 years ago the city solicitor had decided that for a building to have been begun it was not sufficient for the excavation to have been made, but that some of the actual permanent construction of the building must be in place.

STRENGTH OF METAL IN CONCRETE CONSTRUCTION.

Summing up the results of a recent series of tests carried out by the Mininstre des Traveaux Publiques of France, to exactly determine the part played by the metal in ferro-concrete constructions, M. Considere states in a report to the French Academy of Science, that concrete-steel submitted to tension acts precisely as ordinary concrete, so long as the tensile stress does not exceed the usual breaking stress of ordinary concrete. Under higher stresses it will support without breaking extensions which, in the case of specimens hardened under water, have been as great as 1/500th the total length; and, in the case of air-hardened concrete, have ranged between 1/2000th and 1/850th of the total length. When the concrete-steel is stretched beyond the usual elastic range of ordinary concrete, the tensile stress on the concrete remains constant up to the ultimate breaking-point, the whole of the additional load being taken up by the metal. When subjected to repeated tensile stresses, however, the fraction of the load carried by the metal tends to augment, and that of the concrete to fall, until ultimately the working stress on the concrete is only 70 per cent. of its original value. If finally, after a series of loadings and unloadings, the maximum load is raised 30 per cent., the concrete again exerts a tensile resistance equal to its primitive value.

EVOLUTION IN DESIGN.

In an article in the Magazine of Art for September on modern decorative art as shown at the Turin Exhibition, Mr. Walter Crane says: "There appears to be a law of evolution working in the arts of design quite as inevitably as in the natural world. Certain germinal motives, derived from forms in nature or art, are combined by the fancy of the designer. A conflict for pre-eminence, a struggle for existence, takes place in the mind of the artist, as his hand records the stages of the evolution of his design, either on paper or in some plastic material. In view of his ultimate purpose—the use and destiny of the design—certain lines, certain forms, prevail over others as the most fitting; the design sheds inessentials and takes final shape. It may closely follow the principle of its inception, or it may, passing through a multitude of complex stages, finally be evolved in some very different shape; but in either case its development proceeds much as the development of a plant from its seed germ to its full completion and flower, always strictly adapted to its environments. I would not say that forms of design, say surface design, are always so strictly adapted, and one must always, of course, allow room for individual caprice and wilful extravagence and the desire for originality. The limits, however, of even these apparently spontaneous impulses are more restricted than might be supposed. Efforts to be new and original sometimes lead to results curiously similar in form to work of former epochs, where the constructive principle in design has been obscured. For instance, I noted in more than one new art restaurant building in the Parc Valentino (near the exhibition buildings) that which, in its general masses and distribution of ornament, in its absence of rectangles or verticals, or constructive feeling, curiously recalled buildings of the late eighteenth century, or what would be called in Hungary 'Maria Therese' type. Extremes meet, and our twentieth century new art touches, in its least consciously artistic form, the rococo decorative confectionery of the palaces of the eighteenth century.

A FIRE TEST FOR ROOFS.

Tests were recently conducted by the British Fire Prevention Committee of a slated roof and ceiling and a flat roof covered with vulcanite roofing and ceiling. The test lasted one hour, the temperature reaching 1,700 degs. Fahr., followed by the application of water for three minutes. Each floor was 100 feet super., and four weeks were allowed for construction and drying. The slates were "American green," measuring 20 in. by 10 in. by 3-16 in. thick, with a 2½ in. lap, and the ridge covered with blue Staffordshire ridging. The laths were of sawn spruce 1¼ in. by ¼ in. Gutters lined with No. 14 gauge (Vielle Montagne) zinc. The Vulcanite roofing was covered with 2½ in. of gravel and sand. The following is a summary of the effect of the fire:—In fifteen minutes the plaster to the ceiling of the slated roof began to fall; in twenty minutes the inside of this roof was well alight; in forty minutes the plastering of the Vulcanite roof began to fall; in forty-one minutes the slates on the other roof began to fall; and in forty-seven minutes the whole of the slate roof collapsed; while in fifty-four minutes the underside of the Vulcanite flat was a sheet of flame, but after sixty minutes the fire had not passed through it, and it was sound enough to walk upon.

NOTES.

The new King Edward Hotel, Toronto, which is rapidly nearing completion, is being elaborately decorated. It is understood that for the figure work in the dining room living models were employed. The furnishings, many of which are being purchased abroad, are also of an artistic and expensive character.

Work is to be begun at once on the rebuilding of the fallen Campanile, at Venice. Expert examination has proven that the foundations are intact and sound and can be utilized with perfect safety. Three hundred thousand dollars have already been subscribed, one-half of the estimated cost of rebuilding.

The authorities of Paris have recently established a scale of architects' fees for municipal work, as follows:—for buildings costing more than $160,000 4 per cent. on the cost; for buildings costing $120,000 to $160,000, 4½ per cent.; for buildings costing from $80,000 to $120,000, 5 per cent; from $40,000 to $80,000, 5½ per cent.; under $40,000, 6 per cent. The right is reserved to increase or diminish the fee as the character of the work may justify.

"I am old-fashioned enough," says Mr. John Slater, Vice-President R.I.B.A., "to think that an architect ought to try to make his building beautiful, and that a protest should be made against what appears to me to be the cult of ugliness which has been growing of late years. There is too great a tendency nowadays to mere eccentricity and originality among the younger men. There have been several buildings erected lately the cleverness—I had almost said the infernal cleverness—of which cannot be denied for one moment; but are they beautiful?"

The restoration of the Madeleine at Paris, which was decided upon about seven years ago, is only now about to be commenced. It is presumed that the recent fall of the Campanile has created alarm for the safety of the structure. It is believed that sufficient data have not been obtained from which to compute an exact estimate of the cost. It has therefore been decided to expend about 40,000 frs. on the erection of a scaffold, which will enable every part of the building to be examined. The structure will be movable, in order that along the four sides of the building the slightest defect in any of the details can be observed. The design for the present building was the work of Vignon, and was adopted because it pleased Napoleon beyond any of its rivals. But a few years before the revolutions two sets of designs for a church on the site were prepared, one by Constant d'Ivry and the second by Couture. The work which is about to be restored was completed sixty years ago.

STANDARD PORTLAND CEMENT TESTS.*

All experiments shall be carried on, as nearly as possible, at a uniform temperature of 65 deg. Fah., except when tests are being made for the purpose of ascertaining the comparative strength of cements required for winter use.

(1) PROPORTIONS.

All proportions shall be determined by weight.

(2) FINENESS OF CEMENT.

For the present, a maximum residue of 10 per cent on the 100 x 100 mesh sieve shall be the test for fineness, and the whole of the cement shall pass a 50 x 50 mesh sieve. The gauge (Stubb's) of the wire shall be No. 35 for the 50 x 50 sieve, and No. 40 for the 100 x 100 sieve. A mechanical sifter, working automatically by jig motion, and thus eliminating personal error, is recommended.

In the case both of hand mixing and sifting with the mechanical mixer, the process shall occupy a definite time, depending upon the weight to be sifted, and the diameter of the sieve. For example, with a weight of 10-oz. of cement, and sieves 8-in. in diameter, the sifting shall be continued 2½ minutes on No. 120 sieve,, 1 minute on No. 100, ¾ minute on No. 60, and ½ minute on No. 50.

The introduction of small weights, such as washers, into the cement, while being sifted, is to be deprecated, as they tend to push an undue proportion of the cement through the mesh, to stretch the wires and to increase to some extent the grinding. Such practice should not be allowed, excepting on works of construction, where there may be a necessity for ordinary rough tests.

The sieves shall be periodically examined with great care, as moisture sometimes collects on the wire, so that when a residue test is made this moisture mixes with the cement, causing a coating on the wires, and often appreciably diminishing the area of the mesh.

The sand for standard tests shall be quartz, crushed so that the whole can pass through a 20 x 20 mesh sieve (wire No. 28 Stubb's gauge), but sufficiently coarse to allow of the whole being retained by a 30 x 30 mesh sieve (wire No. 21 Stubb's gauge).

(3) SPECIFIC GRAVITY.

The specific gravity is for the purpose of determining the degree of calcination of a cement with certainty, and is therefore of great importance. The specific gravity of a Portland cement shall be at least 3.09, and shall not exceed 3.25 for fresh cements, the term "fresh" being understood to apply to such cements as are not more than two months old. The gravimetric system is recommended for the determination of the specific gravity.

Portland cement improves with age, provided it is properly stored and kept in air-tight bags or barrels. Specifications, therefore, should not prescribe only fresh cement.

The following description of the method of carrying out this test is taken from a paper on "Testing of Portland Cement," by Gary, Trans. Amer. Soc. of Civil Engineers, October, 1893:

"The determination of the specific gravity of the cement particles by the volume-meter of Schumann is a well known uniform method. This consists of a glass bottle of about 200 cu. cm. (12.2 cu. in.) capacity, with a calibrated glass tube in its neck. The bottle is nearly filled with oil of turpentine, the tube tightly inserted and filled by a pipette with the same oil to the zero mark of the scale, care being taken that all air bubbles are removed. One hundred gr. (3.5 oz.) of cement is put in through the tube, which is then closed by a cork. When the fluid becomes clear, the height of its top surface is noted on the scale. The weight of the cement divided by its volume, as determined by the scale of readings, gives the specific gravity. To secure precise results, it is necessary that the temperature should remain uniform throughout the experiment, and hence vessels, cement and oil must have been kept in the same room for some considerable time. In hot weather the apparatus can be put into water of a known constant temperature. If 100 gr. of cement are used, a rise of 1 deg. Cent., between the two readings decreases the specific gravity 0.8 per cent."

(4) BLOWING TEST (FOR FREE LIME, ETC.)

The hot bath test for detecting the presence of free lime, etc., shall be carried out in the following manner: Mortar pats, prepared of neat cement and thoroughly worked, shall be troweled upon ground glass plates (carefully cleaned, preferably with acid) about 5 inches long by 2½ wide, and ¼ inch thick, so as to exclude all air and moisture.

The pats shall be about ½-in. thick in the centre, and shall be worked off to sharp edges on the four sides of the plate. They shall then be covered with a damp cloth and allowed to remain in the air until set, after which they shall be placed in vapor in the Faija bath tank, in which the water is to be heated to a temperature of about 130 deg. Fah. After remaining in the vapor for 6 hours, including the time taken to set in air, they are to be immersed in hot water, and allowed to remain there for 18 hours. Upon their removal from the bath, the samples should not be curled up, should not have fine hair cracks nor be distorted, and should not have large expansion cracks. The samples, if separated from the glass, should break with a sharp, crisp ring. If these conditions are satisfactorily fulfilled, it is believed that no free lime is present in a form that will prove detrimental. Cements, when very finely ground, even if slightly overlimed, are not so liable to blow.

(5) TIME OF SETTING.

The time of setting shall be determined by noting the time required for a sample under test to bear a needle of 1/12-inch diameter loaded with one-fourth of a pound, and one-twenty-fourth of an inch in diameter loaded with one pound, the mortar under test being of the consistency of rather stiff plaster or mortar. The percentage of water used shall be stated in the report.

(6) TENSILE AND COMPRESSIVE TESTS.

The strength of Portland cement shall be determined by testing a mixture of cement and quartz sand. The tests shall be made in a uniform manner (both for tension and compression) with briquettes of the same form and same cross section and with the same apparatus.

Neat cement. Neat tests, except where fineness, specific gravity and hot bath blowing tests are also made, are misleading as to the value of a cement. Briquettes of neat cement, in which these characteristics have been determined and found to be satisfactory, shall bear a tensile stress of 250 pounds per square inch at the end of three days; 400 pounds per square inch at the end of seven days, and 500 pounds per square inch at the end of 28 days. All briquettes shall be one day in air, under a damp cloth or in a damp chamber, and submerged in clean water for the remainder of the time periods. Any cement which shows a decrease in strength on or before the 28th day is to be rejected. The decisive tests shall be considered as the average of five briquettes, although for ordinary practice two or more briquettes may be sufficient, and, in the latter case, only the highest test of the group is to be taken as the strength of the cement.

In determining the tensile strength of a briquette, the area of the broken surface shall be measured with great accuracy, as errors sometimes exceeding 10 per cent. are possible unless such measurements are insisted upon.

Sand and Cement. In sand test, the sand and cement must be thoroughly mixed together while dry. After the water has been added, either for neat or sand tests, the mortar shall be thoroughly mixed for a uniform time; suitable periods being two minutes for machine mixing and five minutes for hand mixing.

Briquettes made of one part cement and three parts standard sand, in the manner described hereafter, shall stand 125 lbs. per square inch at the end of seven days, and 200 lbs. at the end of twenty-eight days.

At the end of the same period the minimum compressive strength of a mixture of one part cement to three parts sand shall be 2,000 lbs. per square inch.

[Note. Quick setting cements generally show a lower strength than that specified above.]

The tensile strength of briquettes mixed in the proportion of 3 to 1, or of other sand briquettes, shall not show a decrease either on the twenty-eighth day or subsequently.

In every case the quantity of water used in mixing shall be stated in the report.

The quantity of water to be used in neat tests varies with the kind of cement, fineness, etc., and hence no arbitrary quantity can be specified, the correct method being to bring all mortars to the same degree of plasticity. An apparatus similar to "Vicat's," and consisting of a needle having an area of 0.4 square inches weighted to about 11 oz., may be used.

"The tests are made as follows: A ring, 1½-in. in height and 3-in. in diameter, made of non-absorbing material, is placed on a glass plate and filled with the mortar to be tested, the consistency being such that the needle does not entirely pierce it." (Trans. Amer. Soc. Civil Engineers, Oct. 1893.)

A simple method for determining the standard consistency neat cement tests is to mould a ball of mortar in the hands to a plastic state and drop the same about 20 inches on to the table. If the ball of mortar neither flattens appreciably nor cracks, the consistency is satisfactory. This process corresponds practically with the previous method. The water for standard consistency of 3 to 1 sand briquettes shall ordinarily be 10 per cent. of the sand and cement by weight. If the amount of water for standard consistency of neat cement of any particular brand be less than 20 per cent. then the amount of water for standard consistency of 3 to 1 sand briquettes for this particular brand shall be one-half of the amount used in neat tests.

(7) PREPARATION OF BRIQUETTES.

(a) HAND-MADE.

(1) Neat Cement. The moulds shall be slightly oiled on the inner side and placed upon a metal or glass plate. The mixture of cement and water shall then be thoroughly worked together (preferably in a Faija's mixer) for five minutes. The moulds shall then be filled well above the rim, so that the mortar presents a convex surface. With an iron trowel the mixture shall then be patted, commencing at the side, first gently and then harder until it becomes elastic and water appears upon its surface. No after addition of the mixture shall be allowed, as the briquettes must be of uniform density throughout. The superfluous cement shall then be removed and the surface smoothed by means of a knife or sharp-edged trowel. The moulds can only be removed when the cement has hardened sufficiently. The briquettes shall then be placed in a damp chamber (zinc lined) furnished with a lid (also zinc lined) to prevent the irregular drying of the briquettes under varying degrees of temperature. After a period of 24 hours the briquettes shall be laid in water and kept completely submerged during the whole period of hardening. The proportion of water used shall be stated in the report.

(2) Sand and Cemnet. Five pieces of blotting paper soaked in water shall be laid upon a metal or glass plate, and upon each piece of paper there shall be placed a mould, also moistened with water. The cement and sand in their specified proportions shall then be thoroughly mixed together, after which the water shall be added, and the whole thoroughly worked for five minutes. With the mortar thus obtained each should be filled by one application so as to rise in a convex form above the edge of the mould. With an iron trowel the mortar shall then be patted, beginning from the side, first gently, then harder, until it becomes elastic and water appears upon the surface. No additional material must be added, as the briquettes must show a uniform density throughout. Superfluous mortar shall then be taken off by means of a knife or sharp-edged trowel, and the surface smoothed.

The moulds shall then be carefully removed and the briquettes laid in a damp chamber (zinc lined), furnished with a lid (also zinc lined) to prevent irregular drying. After a period of 24 hours the briquettes shall be laid in water and shall be kept completely submerged during the whole period of hardening.

(b) MACHINE-MADE.

(1) If possible, briquettes prepared as above shall be subjected to a uniform specified pressure (say, for example, 20 lbs. per square inch) by means of a ram of the same gauge as the moulds, or,

(2) A Bohme apparatus may be used. In this case, the moulds shall be filled with about 4-10ths of a lb. of mortar, prepared as in (a), and shall be placed in the machine; 150 strokes shall then be applied to the core with a hammer of about 4.4 lbs. in weight (2 kilog). After removing the mould and the core the briquettes shall be smoothed off, taken off the subjacent plate and treated as in (a).

By care in following the instructions given in (a) and (b) it will be found that hand work and machine work will give fairly uniform results. Doubtful cases, however, should be invariably decided by machine-made briquettes.

(8) TESTING MACHINES.

Testing machines shall be of the positive lever automatic type, so arranged as to apply the loads quietly and uniformly at the rate of 200 lbs. per minute.

(9) CLIPS.

The style of clips shall be such as will break the briquette at the line of least section. Clips with adjustable rubber or paper composition rollers are found to work satisfactorily and should be used.

(10) CHEMICAL TESTS.

Chemical tests and full quantitative analyses are strongly recommended; and preference will be given to cements of which analyses are furnished by the manufacturers.

(11) ADULTERATIONS, ETC.

Any cement containing adulteration shall not be accepted as a Portland cement. There are also certain ingredients which should be strictly limited in their amount. If there is found to be more than 2 per cent of sulphuric acid or 3 per cent of magnesia, the cement should be rejected. It is understood that Portland cements only are being specified for. The silica or sand cements are in a class by themselves, need special specifications, and are not intended to be included in the present one.

(12) PACKING.

Cement shall either be packed in paper-lined, air-tight barrels, well constructed and hooped so that, under ordinary conditions of handling, no cement shall sift out, or if in sacks, the texture of the sacks shall be so strong and fine as not to permit of any sifting out or wasting of cement under ordinary conditions of handling. The net amount of cement, deducting the weight of the package, shall be 350 lbs. per barrel.

(13) CERTIFICATE.

The manufacturer shall give a written certificate with each shipment of cement, stating (1) the date of manufacture, (2) the tests and analyses which have been obtained at the manufacturer's laboratory for cement taken from the day's grinding of which this shipment forms a part, (3) that the cement does not contain any adulteration.

RECOMMENDATIONS.

Frost Test on Cement. In case of experimental tests made for the purpose of determining the action of cements when exposed to severe frost, it is recommended that the cements be mixed at a temperature below freezing, with cold water, cold sand, and kept exposed to ordinary winter weather, just as they would be exposed in actual construction of masonry. A description of what is done in this connection should be kept for comparison with other results, and the records of such experiments filed with the secretary of the Canadian Society of Civil Engineers.

It has been observed in hot bath tests that little pustules or eruptions take place on the surface; instances are also given of the glass shattering in the hot bath test without separating from the cement or without any other sign of failure on the part of the cement. Members of the society are requested to observe the causes or reasons therefor and report the same to the secretary of the society.

Inasmuch as small consumers are rarely able to gauge or mix their test specimens with a mechanical mixer, it is advised that where tests are made by hand-mixing, due discrimination shall be made in comparing the results with tests made by mechanical mixing. Hand mixing done by an expert will probably agree closely with mechanical mixing, but for ordinary testing the mechanical method will give more uniform results, inasmuch as no skill or dexterity is required to produce approximate uniformity.

Cement testers, where possible, should make long time tests to see whether or not there is any connection between high early tests and future falling off in tensible strength, and whether, when mixed three to one with sand, the same or similar deterioration is observed. These tests should, if possible, be carried on for several years. It would be of the utmost value to the profession to obtain positive data on this point from engineers in charge of municipal university or other laboratories, who are in a position to supply it.

*Report of special committee submitted to Canadian Society of Civil Engineers, January, 1902.

The sudden death is recorded of Mr. Thomas Mowbray, a well known sculptor, of Toronto. Before coming to Canada the deceased executed carvings on some of the most important public buildings of Liverpool, Eng. The Toronto Custom House shows examples of his skill.

Mr. J. O. Marchand who for nine years past has been engaged in the study of Architecture at the Ecole des Beaux Arts in Paris, has returned to Montreal, his native city, and in conjunction with Mr. Stevens Haskell, of New York, has commenced the practice of his profession there. The firm have opened offices in the London and Lancashire Building, St. James Street.

BY THE WAY.

The announcement that a manufacturing company has leased until August first next, the Machinery Hall on the Industrial Exhibition grounds at Toronto, as a storage warehouse, paying therefor a rental of $300 per year and for extra insurance, suggests the enquiry: Why might not the other important exhibition buildings be thus utilized for ten months of every year and made to yield a revenue?

× × ×

"It is especially easy for a plumber to lose his reputation for good workmanship," said a prominent member of the Guild. "After you have as you suppose put in the very best materials and workmanship, the system has perhaps no sooner gone into use, than lo! a leak develops, due to a flaw in the tap, and straightway the plumber's work is condemned and his reputation with that particular customer at least has suffered, and through no fault of his own."

× × ×

The fall of the Campanile at Venice serves to confirm the old adage that declares: "It's an ill wind that blows nobody good!" The accident has created a general feeling of alarm regarding the safety of the other famous structures of the city. Investigation has apparently been started none too soon, for it is said that cracks and fissures have been discovered on every hand and the wonder is that the walls of some of the buildings have held together so long. During a recent service in the Church of St. John and St. Paul the capital of a small window column fell from its place and created a panic. The prospect before the builders of Venice is most encouraging.

⁂ × ×

In the Middle Ages many of the principal buildings, devoted to religious uses, were designed by monks. Interest in architecture by the clergy of the Roman church continues to the present, but as a rule the designing of their buildings is entrusted to architects in regular practice. It appears, however, by an announcement in the press that the Rev. Father J. Bouillion, Canon of the Roman Catholic Cathedral at Ottawa, Ont., has prepared and had approved by a religious community in New York plans for a church edifice of colossal proportions, to be called the Nova Sancta Sophia. Accommodation has been provided for 60,000 or 70,000 persons. The structure is to be surmounted by a dome 420 feet above the ground, while the interior is to be enriched with columns of rare marbles and costly mosaics.

PATENT STORE FRONTS.

One of the new inventions, covered by half-a-dozen patents in the U.S. and Canada is the Coulson Corner Posts and Transon Bars. This is of great importance to all architects and builders, and a large number have already been ordered for different points in Canada. The great feature of this invention is that plate glass can be put in from the outside. It has the advantages of least obstruction to light, greatest strength for holding large windows safely, and least danger and trouble in setting or replacing large plate glass.

Instead of a heavy wood frame, "The Coulson" is made of a narrow light piece of soft wood set into a groove, in the back of which the angle of a steel T-bar is sunk and firmly fastened by lag screws. The glass being set and firmly secured by wooden stops the advantage of an all-wood bearing for the heavy plates is secured with the rigidity of the iron T-bar added. The face of the posts and bars, together with the wood stops which make up the outside may be covered with polished brass, sheet aluminum, oxidized nickle plate or copper sheeting, firmly screwed to the wood after the glass is set, presenting a beautifully neat and light appearance of a single metal or wood strip between the several plates of the window.

For artistic windows, for economical and effective displays or advertising this new invention is especially useful and we predict a large sale throughout Canada.

The Metropolitan Plate Glass Insurance Co. of N. Y. made a thorough investigation of the Coulson and they have highly commended its use to all architects and builders. They also stated that the invention was the very best to lessen losses occasioned by handling plate glass.

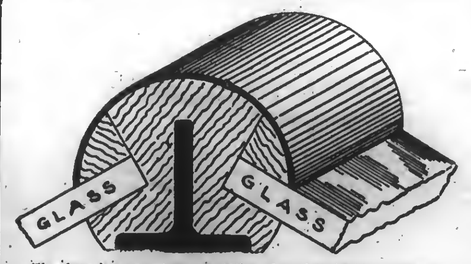
A visit to the works of the Coulson Co. show a busy section of the city of Columbus, Ohio. They will be pleased to send their illustrated book to all applicants.

WARNING TO CONTRACTORS

THOMAS McLAUGHLIN,
16 KING ST. WEST, TORONTO, ONT.,

SECRETARY-TREASURER of RAVEN LAKE PORTLAND CEMENT COMPANY, LIMITED, is the sole authorized Agent for CANADA for Palmer's Patent Hollow Concrete Building Blocks and Building Block Machinery. The Walls of the Dairy Building and the Foundation of the Art Building on the Exhibition Grounds are fair examples of what can be done in one department of building by the use of Palmer's Patent Hollow Concrete Building Blocks. For Machines and Exclusive Territory apply to our Canadian Agent at address above. All infringements will be prosecuted and, therefore, Contractors, Property owners and others will avoid trouble and expense by consulting our authorized Agent before using our Patented Hollow Blocks or Machines.

HARMON S. PALMER, Washington, D. C.



The above is a correct representation of our full size No. 13 corner.

for new or remodeled store fronts.

Greatest strength for holding costly glass safely.

Strongly recommended by the Plate Glass Insurance Co.'s and all architects.

J. W. GOULSON & CO., 96-98 N. 3rd Street, Columbus, Ohio.

THE MERCHANTS' BANK OF CANADA, WINNIPEG.

The extraordinary progress made by this energetic western city prompted the Merchants' Bank to be in the very van of business, and with the fullest faith in the permanence of this progressive movement, decided to erect a substantial 8-storey fire-proof bank and office building, on a splendid site at the corner of Main and Lombard streets.

The designing of this important work was entrusted to Mr. Andrew T. Taylor, F.R.I.B.A., architect, of Montreal, who has designed many bank buildings throughout the Dominion. Most of the ground floor is occupied by the bank, and the other floors are all laid out as offices. The subsoil in Winnipeg is a somewhat soft clay, and as this is probably the heaviest building for its area that has been erected there, special precautions had to be taken with the foundations.

The ground storey is of fine cranelled creamy white Indiana limestone on a plinth of granite; above that the storeys are of a fine toned red pressed brick from St. Paul, with a great deal of stone dressings, and surmounted by a very elaborate and handsome ornamental copper cornice.

The banking room is handsomely finished in antique oak and marble, and has an ornate and rich elliptical arched ceiling. The floor is of ornamental mosaic, and the large windows afford magnificent light. The vaults are strongly and elaborately built, and nothing has been spared to make the building complete in every respect. Two electric elevators supplied by The Fensom Elevator Co. of Toronto, give rapid service to the offices. The elevator enclosures are of very handsome ornamental design, being of specially designed wrot. metal and finished in antique brass.

The staircase is of iron and marble. The entrance is lined with rich marbles. The staircase goes up to the roof, and as this is the highest building in Winnipeg, a very extended view is obtained of the city and surrounding country. The offices are finely finished in hardwood, with plate glass windows and hardwood floors.

The general contractors were Messrs. Black & Co., of Winnipeg. The bank fittings were executed by the Canadian Office & School Furniture Co., of Preston, from designs by the architect. Mr. Frank Peters, of Winnipeg, and Mr. Robert Wilson, have very efficiently superintended the work.

DR. ROBERTSON, President. J. S. McCANNELL, Managing Director.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

A Russian nobleman is said to have built of paper a house of 16 rooms upon his estate at Savinowka, in Podolia. This house was made in New York, at a cost of 80,000 roubles, and its architect declares that it will outlast a stone building, which is quite creditable when one reflects upon the rapidity with which some of our stonework is disintegrating from the action of rain, frost and heat. Bergen, in Norway, has a church built of paper, capable of seating a thousand people.

Owing to its remarkable hardness, elasticity and durability, it rivals the best wax finish, but is free from its unpleasant slipperiness.

Moving furniture or boot heels do not leave white marks, nor does soap, mud, or water destroy its fine appearance.

It dries dust proof in about three hours.

Being very penetrating it closes the pores of the wood against disease germs, making it invaluable for hospitals, asylums, and similar institutions.

Architects patronize home industry and specify Granitine Floor Finish.

To our readers every one we wish a Joyous Christmas and a Happy and Prosperous New Year.

Students' Competition.

Attention is directed to our Students' Competition for a Suburban or Town House, to cost $2,500. Particulars of this competition were printed in our November issue and again appear in the present number. It is hoped that architects throughout the Dominion will call the attention of their students to this competition and urge them to enter. An opportunity is afforded every student to test his powers and to learn where he stands in the ranks of the coming generation of Canadian architects.

Architects' Assistants.

The supply of competent men in this line is at present much below the demand. A few years ago hundreds of draughtsmen were looking for positions. To-day all whose services are worth having are steadily employed at good salaries. There are a few floating about looking for employment, but they are the kind that no architect of standing would wish to have in his office. They either lack a proper understanding of the work that a draughtsman is expected to perform, or are so careless in their methods that they cannot be relied upon. A man belonging to this class on being sent to take measurements of some old buildings to which additions were to be made, was found to be out more than two feet in his figures showing the width of the building, which had a frontage of only 70 feet. Inaccuracies scarcely less glaring marked his other measusements, so that it became necessary to do the work over again. Such "ass'stants" are simply a stumbling block and a source of annoyance to architects.

Close Planning.

In these times of high prices for labor and material, the architect who desires to save his clients' money will give the most careful attention to the preparation of his plans with the view of securing the necessary accommodation within the least possible area. This is especially necessary in house planning, owing to the more costly interior finishings. In this class of work every additional two feet of area will add about six per cent. to the total cost of the structure. The necessity for the closest planning is therefore apparent. As regards the cost of building, there is nothing to indicate cheaper prices. On the contrary, there seems a probability that they may go still higher. Brickmakers have been unable to obtain fuel, and the kilns in the vicinity of Toronto are said to contain millions of unburned stock, which will not be available this year. This will probably mean an advance in prices next spring. The demand for iron and steel has been so great that the output of the mills for a year to come is said to be already contracted for. These facts would seem to prove th

co tinuance of the present era of high prices for at least a year to come.

Canada's Development.

CANADA has entered on a period of development which seems likely to rival that of the United States. Almost every day brings news of some colossal enterprise, and we are becoming so accustomed to such announcements that as a rule we receive them with but very moderate surprise. The declaration however by the authorities of the Grand Trunk Railway Company of their purpose to begin immediately the construction of a line by way of the Peace River Valley to the Pacific Coast, has naturally awakened the deepest interest from one end of the country to the other. The announcement is a declaration of confidence in the future of our great northwest territory that must greatly redound to the benefit of this country. The expenditure of something like $100,000,000 in the construction of the new transcontinental line will help to extend and maintain for some time to come the prosperous conditions now prevailing, while the inflow of population following the opening up of a vast and fertile territory, will permanently broaden the market for manufactured products. The future greatness of Canada seems now to be assured and considering the rapid movement of events in these days, another decade will probably witness its realization.

Is Your Wiring Safe?

THERE have been a great many fires lately in Canadian cities whose origin has never been satisfactorily determined and which have consequently been blamed on that force, to the layman so mysterious and uncontrollable, which is called electricity. The popular verdict may be right, or it may be wrong, but the fact remains that a large proportion of the electrical installations in this country, more especially the older ones, are in a state so dangerous that it is simply amazing. As instances, may be cited a warehouse which, devoid of attendants 90 per cent. of the week, and filled with cotton and woollen millstock, was wired without an entrance switch and equipped with the ordinary link fuses, absolutely open. The chances of a melting fuse igniting the bales not over eight feet away and directly below them were so great as to amount almost to a certainty; in fact the woodwork bears evidence of one fire which has already occurred and which was due, so we are informed, to electrical causes. Another case is a church in which the wiring, ramifying all over and through the building, mostly wood, and minus any attempt at bushing either with porcelain or even rubber at the many points where it passes through walls and floors, is supported by wooden cleats in its many wanderings past gas, water and furnace pipes of all descriptions. Investigation would probably show many such installations as these; is it any wonder that fires occur in them? Rather is it not a source of surprise that so few fires occur, especially when we consider the many chances that exist for line crosses, transformer breakdowns and lightning discharges bringing into the building potentials which are not only much greater than can be controlled by the insulation of the circuits, but which in addition are dangerous to life. A stitch in time saves nine; if you are a consumer why not spend the comparatively small amount necessary to put your wiring in good shape, at any rate have it periodically inspected; if you are a producer look carefully to your own lines, especially those in the station itself, in addition urging upon your customers the necessity of keeping careful track of the electrical material, both new and old, both machinery and wiring, which they may from time to time have upon their premises. If these precautions are taken, the public will gradually become less skeptical of electricity as a fire hazard. There is no reasonable man who does not acknowledge that electrical illumination and electrical power, compared for instance with oil and gas, are not only the most artistic and convenient, but far and away the safest, it therefore behooves us all to see that as far as in us lies, due precautions are taken in the installation of this method of illumination.

Government Architecture.

THERE is a marked contrast between the architecture of government buildings in the United States and in Canada. The designs for public buildings prepared in the office of Mr. J. Knox Taylor, Supervising Architect, at Washington, rank among the very best examples of modern work done in the States. Evidently Mr. Taylor is himself a master of his profession, and has under his direction a staff competent to give effect to his ideas. We regret to say that in Canada the opposite conditions seem to prevail. Many of our government buildings erected in recent years are atrocities in design—the work in some instances of engineers—or stupidly commonplace and uninteresting. The latest example is the new chemistry building for the School of Practical Science, Toronto, the principal elevation of which was published in the illustration pages of our November number—rather an example of what to avoid than of what to follow. The design for this building is entirely unworthy of the splendid site which it will occupy. Besides showing an entire disregard of harmony of style, the design is in other respects lamentably weak, and perfectly lacking in interest. To particularize but briefly, we need only direct attention to the diminutive pediment in the center of the facade dominated on either side by larger ones, and to the character of the window openings in the upper stories. Realizing the importance of the building and the site, the Ontario Association of Architects urged the government to institute a limited competition for designs among leading architects in private private practice. This suggestion having been declined, the privilege was then requested of examining the designs to be prepared in the Department of Public Works, and of making any suggestions for their improvement that might seem desirable. While this request was not refused, no definite information was vouchsafed as to when the plans would be ready, nor was a proper opportunity given for their examination a protest of the Toronto Architectural Eighteen Club was likewise disregarded. It was apparent that no outside suggestions or interference was desired. The result is before us, and is such as to confirm the rumor that this department of the Government service is run on political lines, and affords a shelter for incompetents and "has-beens." It is time for a change which will secure beauty as well as utility in our public buildings.

GARGOYLE, CREWKERNE, SOMERSET.

OFFICE MANAGEMENT.

A series of excellent articles, on the business side of an architect's office, which have been coming out during the current year in the Brickbuilder, are worth reviewing and condensing for the use of architects in this country.

Method is essential, even in a small practice, and the different heads under which office method is here outlined must have place in some form in every office, if work is to go smoothly. It is better, as the author of the articles in the Brickbuilder says, to adopt, at the beginning of a small business, a comprehensive scheme which may be expanded, so as to avoid making revolutionary changes at a later date.

FILING is the first thing to be considered; to keep the letters, drawings and other documents, so that they may be surely and easily produced for use. The great thing is to keep everything that relates to any given building in receptacles devoted exclusively to that building, all marked with its mark. The most convenient mark is a number; the number which that commission bears in the office history. This marks the position of all files of this building in the set of files of their kind. The number serves for both file number for orderly arrangement and as a means of indentification for every kind of document relating to the particular piece of work so numbered.

In connection with the file system two card catalogues are necessary. One is an index of addresses and the other of drawings. In the address catalogue tray every name connected with the office work or correspondence is inserted in alphabetical order and the card bears, below the name, the nature of this connection. Thus, John Smith who has below his and address—

"13—Residence on St. George St."

19—Stable on Huron St."

is a client for whom were done works 13 and 19. John Smith who has below his name and address—

"13—Plumbing and Heating,"

was the contractor for those works in the residence of the other Mr. Smith on St. George St. If there is another John Smith who has done nothing but introduce a friend, his letter and reply will be found in the miscellaneous letter file.

If then Mr. John Smith the owner writes about something on the second floor of his residence on St. George St., anybody in the office can find the drawing or any document relating to the question, by looking up Mr. Smith in the address tray and getting file 13 of the kind of document required. If it is a drawing he may refer first to the drawing catalogue. Here the raised guide card, marking off the other cards relating to this building, is marked "13 John Smith, Residence", and is of course in its numerical order in the tray. All necessary information about John Smith and his building may be written on this card against printed headings of location, description (brick, frame, etc.) total cost, cubical contents, cost per cub. ft., date of first contract, date of last certificate. After this may come a card, if the building is of any size, giving the scheme of numbering for the drawings. Thus, preliminary sketches may have a letter prefixed to them; if there is more than one series of these sketches they will be marked A, B, etc., before the drawing number. Then, when the design is settled, the working drawings may be subdivided, on the same plan that rooms are numbered in large buildings, so that the number itself indicates where to look for it, thus:—general drawings, 1-99, iron 100-199. plumbing, heating, electric light, etc., 200-299, scale details 300-399, full size details 400-499, etc. This being done each card may be filled with numbers—five on each side would make a convenient progression for turning over rapidly, as each card will count ten. The five numbered spaces on each side should be ruled off from one another and have also spaces left to enter the dates of beginning and approval of the drawing, the scale and the draughtsman. Here, as in all other forms, everything that is fixed should be printed; not only to save labour but as a perpetual reminder of what must be recorded.

LETTERS.—The modern practice is not to copy letters in a letter book, but to typewrite them in duplicate and file letter and answer together. With the increased use of stenographers and typewriters, correspondence may be made and should be made a complete record of business. Every time the owner gives instructions he should receive a letter accepting the instructions; every time a warning, or instruction, or order is given to a contractor a letter ought to record it.

DRAWINGS.—The stamp for drawings should have spaces headed as recording the initials of the maker, tracer and reviser, the date of the drawing, its building number, drawing number and issue numbers, besides a space to letter its descriptive title and scale. The architect's name and address will of course be part of the stamp. The essentials for filing, and for record in the issue book, are the numbers.

Drawings must be kept flat. It has been customary to do this by keeping them in portfolios and this has advantages for facility of handling folded drawings; but hanging appears to be the modern way, and it is certainly better for frequent handling. The drawings are clipped in files after the manner of newspapers and can be hung very close together, end on to the back of the closet. A closet a little more than 3 feet or 3 feet 6 inches deep is necessary and all drawings must be made or folded to hang from a file of this length. Hanging in this way, according to building numbers, and drawing numbers, drawings are easily found and used. Full sizes larger than the standard size of the file should be drawn on paper which is a multiple of that size, so that they will fold to match the other drawings. Bond paper 27" x 40" with a blank title printed in one corner, is in use for full size details, in the office of Messrs. Cope & Stewardson. These sheets are said to give good prints from lead pencil lines. Most details can be got upon paper of this size, and others can be folded to the same size. It is a great help to draw some details not only full size but at full length, but a drawing of this kind is intended

only to help the designer : it is a study, and is better condensed afterwards in small form for the working drawing, which needs nothing but the details, and which has to be handled and copied and filed.

BLUE PRINTS.—The articles in the Brickbuilder do not take notice of blue printing in the architect's office. There are blue printing establishments to which the work is sent out, and which render monthly accounts based on a charge per square foot. Orders are sent out by means of an order book made of alternate yellow and thin white leaves. By means of carbon paper and lead pencil the order is written in duplicate. The perforated yellow leaf is sent out with the drawing and the white book-leaf remains, to be used in checking the monthly account. Both yellow and white leaves are ruled and printed in the same form with headings under which to note the essential points, viz., the order number and date, the building number, the sheet number, the number of copies required, the kind of print (blue, black, etc.), the material (paper or cloth) and the size—first in the dimensions required and again decimally in square feet. This last column, when totalled on all the order slips of the month, gives immediately the means of checking the amount of the monthly bill.

ISSUE AND RECEIPT OF DRAWINGS.—A book should be always at the office boy's hand, ruled for record of drawings sent out. The headings of the rulings would be the issue number, the building number, the drawing number, title and description (tracing, print, etc.), the purpose of the issue, the issuer and the dates of issue and return. Receipt forms should be sent with the drawings, and if a receipt is not returned another form should be sent out. The guide in this case is the issue number. The entries in the book and the receipts filed are in the order of the issue number, and this number should be marked on a drawing when it is sent out. Every time it is sent out it will receive a new issue number. When the drawing is brought back the issue number points to the place where credit should be given, and the date of return is entered instantly. To find out where a given name or a given drawing are in the list, in answer to an enquiry whether certain contractors have received a drawing or where a certain drawing is, it is necessary to run the eye down the list of names or drawing numbers. This is said to be rapid enough.

W. A. LANGTON.

ORIGINALITY OF DESIGN IN ARCHITECTURE AT THE EXPENSE OF BEAUTY (SLATER)—HOW SKY-SCRAPERS CAN BE MADE MORE AESTHETIC.

Editor CANADIAN ARCHITECT AND BUILDER:

SIR,—Under "Notes" in your last issue, page 135, you cite Slater, vice-president R.I.B.A., as saying that "there is too great a tendency nowadays to mere eccentricity or originality amoog the younger architects, while beauty of design or aestheticism is neglected."

There is abundant truth in this, as witness many of the designs for even pretentious dwelling houses, which would be more appropriate as club houses at fishing and sporting stations in our forest reserves.

In your "C A. & B. Students' Competition" at page 130, for the design of a dwelling house on a 50 foot lot, you very properly advise students that the adjoining buildings are within 10 feet of their respective boundaries, thereby leading them to infer that the proposed building should also fall short in its dimensions of the whole frontage of the lot to be built upon. This is most essential in certain cases, for light and air on all sides, and more especially where costly structures to show to advantage must be kept away or isolated from adjoining buildings, except of course along the business streets of a city where land is expensive and every foot of it has to be made available.

If Mr. Slater would, when he visits Quebec, take a walk along our "Grand Allee" or St. Louis road, he would, while deprecating eccentricity of design in a certain house with a most fortress-like basement, deplore the vicinity of such a costly structure to those on either side of it. In fact it so abuts on or against the gable end of the house adjoining it to the eastward that one cannot tell whether the more salient and ornamental turrets and chimney stacks of the former belong to it or to the latter; it is only when looking at it directly from the street that one can tell which is which.

Now, sir, this is a pretentious building in every respect, said to have cost some $37,000, and it is really a pity that the architect, a Montreal man, did not advise his wealthy patron to purchase a wider lot for such a splendid structure, original though it be in design.

With regard to tall buildings of the sky-scraper persuasion, it is singular how in course of time one can become wedded to such a style of architecture when treated in a way to produce the impression that the building is made up of a lesser number of horizontal sections. Your engraving of the facade of the London Globe Insurance Building, of Montreal, is proof of a good attempt at this, where the two lower floors or stories of the building are so to say combined in a way to look like but one by separating them by a salient cornice from the stories above, and the attic or eighth floor is apparently eliminated by being separated from the floors below by a heavy eave cornice, which I believe it would have been preferable to bring down another story, and thus reduce the intervening five stories to four, while leaving two above the main entablature to form the attic portion of the edifice.

Your engraving also of the splendid new bank for Winnipeg would imply that had the two lower stories been made one of, apparently, which impression would have been given by separating those two floors from the remainder of the edifice by some salient horizontal feature such as a continuous balcony or ornamental bracket, and by making far more salient the cornice between the upper story and the one below it, or even, as in the case above alluded to, by bringing down this cornice in a way to leave two stories above it for an attic; then would also this facade have acquired something of the classical features looked for in building in geoeral where some proportion is looked for between the three horizontal sections of an edifice—it's base or pedestal, it's shaft or main section, and it's capital, entablature or attic.

It must be admitted that where a tall and narrow building, such as there are so many of in New York and Chicago, one absolutely unrelieved in any way by separating horizontal salient features, the thing we look upon is far from being one of beauty; but when, as in the New York Waldorf-Astoria, there is, coupled with great height, a corresponding breadth of base, with a combining of the stories together in threes or fives and even sevens, there may still result a species of aestheticism, which when taken with the absolute necessity in our time for such multi-floored or storied structures render the building less distasteful.

A pertinent example of this is now being given on Broadway, New York, between 73rd and 74th street, where the new Ansonia Department Hotel, so called, which is about 200 feet square, is to be seen, or soon will be, with its 16 story facade broken up into three sections, of which the basement combines the three first floors of the building, the attic or upper portion the two or three upper flats, and the main shaft or middle section, thus reduced to only 8 or 9 stories and in a way, as above inferred, to cause it's facades, thus divided by salient balconies, to become really acceptable from an aesthetic point of view.

CHAS. BAILLAIRGE,
Architect and Engineer.

Quebec, Que.

The Queen City Plate Glass & Mirror Co., Ltd., have made extensive additions to their already large plant.

The Brick Manufacturers of Ontario have organized an Association with the following officers:—president, B. E. Bechtell, Waterloo; vice-president, Robt. J. McCormick, Warwick; secretary, Alex. Johnston, London; treasurer, Henry Janes, Delaware; executive committee, Messrs. J.W. Cawrse, London, and John Karn, Brownsville.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

A series of monthly meetings for the informal discussion of matters of interest to the profession have been arranged in Montreal. The meetings are held on the third Tuesday of each month. There have already been held two meetings. At the first one held in October an informal discussion took place on "Professional Esprit de Corps"; the second held in November consisted of a small dinner and a lecture by Mr. F. G. Archibald on "Legal Responsibilities of the Profession." The lecture which was given with a resume in French by the lecturer, was followed by a discussion on the same subject by the members present. The meetings were very satisfactory as to attendance and interest shown by members. The next meeting which will take place on the third Tuesday in December, will have a specially artistic character. The Council propose to invite to this meeting other artists, sculptors and painters, and there will probably be a conversation on the special features of what is called the "Art Nouveau." At future meetings there will probably be one or two other lectures on legal matters by Mr. Archibald; conversations and perhaps lectures on technical education and other topics of interest to the art and profession are also contemplated, the intention being to make such enterments as broad and varied as possible so as to meet the ideals of all members, whether artists, business men or specialists.

THE PURPOSE OF SCULPTURE.

In a lecture on this subject delivered recently at Cambridge, England, Mr. Alfred Gilbert, R. A., observed that the art of sculpture had many and varied sides, and the more he worked the more he tried to find out which was the right and proper road to perfection. Sculpture was not merely a doing, a making, or the mere expression of a man's idea. It was threefold in its purpose. It was mechanical, to begin with; it was real, to go on with: and it should be—and must be, if it was to carry any message forward—ideal. The work of a sculptor was not merely the work of one who hewed and broke and tried to make. His efforts should be moulded by that something called love, veneration, faith—that love which impelled him to give up everything, to do everything in his power to educate and lead his fellow beings to that extraordinary refinement and delicate perception of the beautiful which alone could be understood by those who love. Pygmalion so loved the image his own brain had created that he longed that the great creation could speak. The sculptor's great object was that his creation should speak—without the aid of an exhibition catalogue. The work of the artist should be the work not only of his art, but of his heart. The function of sculpture was not merely the making of an object. The primary object was to make something beautiful, something that whoever saw it should be elevated by it, something that was not the mere imitation of an everyday person. The more he thought the more was he astonished that the practice and the teaching and the encouragement of the art was so little thought of. The equipment of the sculptor was not sufficiently given in our art schools. The sculptor should be as well equipped as the mathematician, the poet or the architect, by education. He wanted to connect the practice of sculpture with the practice of general education. Until they did tha he was convinced that they would never hope to take rank as artists with the great men among the Greeks, whose excellence was the outcome not only of pure mechanical training and skill, but the influence of great mental power. The artist must read and think, and the more he thought the better artist he was likely to be. He had been twenty-five years in finding out that he knew nothing about the making of a statue. He was only just beginning to know how to approach the exposition of the art, which was to make everything he touched as beautiful as his own unbeautiful nature would allow him to do.

COMPETITIONS.

A competition is announced for designs for a church to be erected in the city of Patras, in Greece, to cost $250,000. The committee having the matter in charge consists of the Metropolitan bishop, the governor of Achaia, and the Mayor of Patras. The conditions of the competition which is understood to be open to the world, are as follows :—

1. The dimensions are left to the discretion of the architect, but must come within a ground space of 2,400 square meters (25,834 square feet).

2. In planning this structure, consideration must be given to possible effects of earthquakes, to which this region is subject.

3. The edifice must accommodate at least 5,000 worshippers, not including standing room in the women's apartments or other annexes.

Possible models of architecture might be found in the Russian Church of St. Nicodemus, in Athens, or in the church of St. Sophia, in Constantinople.

The contest will be divided into two parts; all who pass the first degree will be entitled to enter the second degree, and no others. The general requirements for the first degree are as follows:

1. To submit a general view of the temple and courts on a scale of 1 to 500.

2. View of front of temple : scale, 1 to 200.

3. Two views, front and lateral ; scale, 1 to 200.

4. View cross section, setting forth the general plan, according to the judgment of the artist.

5. Estimate of the cost.

6. An abridged technical memorandum.

The plans submitted will be passed upon by the committee, and the successful architects will be required to meet some additional conditions, among which are the following :

1. View of temple ; scale, 1 to 100.

2. Three views—front, lateral, and rear ; scale, 1 to 100.

3. Diagram showing the principal architectural features : scale, 1 to 100.

4. Two cross sections, with internal views ; scale, 1 to 100.

5. Cross section, showing manner of heating, ventilating, etc.

The contest of the first degree closes at 12 o'clock noon of February 13, 1903. All who have successfully passed into the second degree will be given one hundred and fifty days additional from the time the decision is rendered. The final plans will be submitted to some academy of the fine arts in Europe, and in accordance with its decisions the committee will award a first prize of 10,000 francs ($2,000) ; a second, of 4,000 francs ($800) ; and a third, of 2,000 francs ($400).

TESTS OF CEMENT MORTAR.

The results of a series of tests of cement in connection with the construction of the Wachusett dam are summarized in the report of 1901 of the chief engineer, Mr. F. P. Stearns, who also gives the following notes concerning some special investigations:

In view of the very large amount of mortar to be used in the dam and the importance of having it as water-tight and strong as possible, extensive experiments were begun early in 1901, to determine the permeability and strength of mortars made of the natural and Portland cements which were to be used in the construction of the dam, mixed with different proportions of coarse and fine sands.

The experiments on permeability were made by placing the cast-iron cylinders, 22 inches long and about 6 inches in diameter. After the mortar had set, caps were bolted to the tops of the cylinders and water was admitted to the cylinders between the caps and the mortar with a pressure of 74 pounds to the square inch. There were 144 cylinders used in the experiments, and the apparatus was so arranged that the water pressure could be applied to 24 cylinders at a time. The applied water was first filtered through sand, to remove all suspended matter.

There were 1,494 briquettes made and broken, to determine the tensile strength of the mortars. It was found that the use of a sand with a very large proportion of coarse particles and a much smaller percentage of the finer grades makes a mortar both less permeable and stronger than where a larger proportion of the finer grades is used, provided the proportion of sand to cement does not exceed 3 to 1.

In addition to the experiments upon permeability and strength of mortars other experiments were made to determiue the relative strength of mortars used immediately after wetting and mixing and when used at different intervals up to two hours after they are first wet and mixed. These experiments were very extended, as they were made with mortar mixed with different grades of sand, with Portland and natural cement, with slow-setting and quick-setting cement, and with mortar that was worked continuously from the time of mixing until it was put into the molds and also with mortar which was not worked after it was mixed until just before it was put into the molds. The briquettes were broken at the end of fourteen days, twenty-eight days and three months after mixing.

It was found that when the cement, both Portland and natural, were so manufactured as to take the initial set slowly, the strength of the mortar was not diminished by a delay of two hours in putting it into the molds; and when the mortar was worked continuously to the time of filling the molds, there was an increase in strength occasioned by the delay. When the cements were so manufactured as to take the initial set quickly, the results obtained with the quick-setting Portland cement were not materially different from those obtained with the slow-setting cement, except that when the mortar was not worked there was a slight loss of strength in the briquettes molded at the end of one and a half and two hours, and at no time was there much gain of strength occasioned by delay in filling the molds. The results obtained with the quick-setting natural cement were less favorable, as the briquettes broken at the end of fourteen days showed a great loss of strength when there was much delay in molding the briquettes. At the end of three months, however, the briquettes made with mortar which had been worked continuously from the time of mixing showed slightly greater strength than that put into the molds immediately, and the loss of strength of the mortar not worked was not very marked except for the 1½ and 2 hour periods.

EDUCATIONAL COURSE FOR ARCHITECTURAL STUDENTS.

An educational course for architectural students in Toronto has been arranged by a joint committee of the Toronto Chapter of the Ontario Association of Architects, and the Toronto Architectural Eighteen Club. The fee for is $5.

The course will consist of scientific classes held at the rooms of the O. A. A., 96 King Street, West, and the studio work now carried on at the Central Ontario School of Art and Design.

The scientific class will be held on Thursday evenings, the studio classes on Monday, Wednesday and Friday evenings.

It is strongly urged that all architectural students in the city attend both classes.

SUMMER RESIDENCE, BEACONSFIELD.

This residence for Senator Drummond, an illustration of which appears in this number, has recently been completed adjoining his well-known stock farm and golf grounds, and overlooks Lake St. Louis. Its wide, cool galleries and portico and its great hall, over 40 ft. long, are special features. It is an adaptation of the old Colonial and Georgian style, and is very substantially built of wood on a stone substructure. It is finished in white and primrose and the roof is stained moss green.

The interior is elaborate, and is finished in white enamel, and the walls hung with bright charming Morris papers. The fireplaces and mantels are a feature, and are numerous and large.

The tower was specially designed for an extensive view over Lake St. Louis and the surrounding country.

The work has been carried out very satisfactorily by Mr. John Allan, contractor, from the designs and under the superintendence of Mr. Andrew T. Taylor, F.R.I.B.A., architect, of Montreal.

BANK OF NOVA SCOTIA, TORONTO.

This building, the principal facade of which is shown in the illustration pages of this number, is in course of construction at Nos. 37 and 39 King Street West, Toronto. The front is to be of gray sandstone, the main wall being recessed a distance of ten feet from the street line. The dimensions of the banking room are 85x32 feet; height, 35 feet. This room will be decorated in the Free Classic style which characterizes the building. The scheme of lighting is from the sky. The walls to the height of fourteen feet are to be lined with second statuary marble. Above, a range of Ionic pilasters will divide the wall surface into panels, available for mural painting or other decoration. These pilasters are surmounted with a rich architrave, frieze and cornice. The length of the room is divided into three bays, and the panels offer space for a variety of treatment.

The space reserved for the public is to be laid with mosaic tiled flooring, and the counters will be of marble in contrasted colors, surmounted by handsome bronze grills. The whole of the desks and office fittings are to be of sheet steel, entirely eliminating wood from the structural part of the building and rendering the structure as far as possible fireproof. Messrs. Darling & Pearson, of Toronto, are the architects.

PHOTOGRAPHY AS APPLIED TO ARCHITECTURAL MEASUREMENT AND SURVEYING.*

By J. Bridges Lee, M.A.

Most people are in the habit of looking upon photographs as more or less artistic or inartistic pictures destined to convey impressions more or less accurate or inaccurate of what things look like. Comparatively few people have yet acquired a habit of regarding photographs as accurate measureable records of external facts.

The first important generalisation we can arrive at is that the picture surface can only be an exact copy of the thing depicted when that also is a similar surface, and only then when the picture surface was parallel to the object surface at the time when the picture was taken. We may conveniently regard a photographic picture as a radiant production every point of which is at the end of a straight line coming from an apical point somewhere in front of the picture. Generally that point is somewhere inside the body of the lens, but it may be outside, either before or behind the lens, and it is called the station-point. The picture yielded by the lens is the same as would be obtained by a simple pin-hole at the station-point: a good lens gives a brighter and more sharply-defined picture than a pin-hole, but otherwise the pictures are the same in size and outline.

With this conception always in mind that a photographic picture is a collection of points at the ends of straight lines radiating from the station-point in the same directions as corresponding straight rays of light which have originally travelled from the objects depicted to that point or its adjacent counterpart, a correct understanding of many of the problems of photographic geometry becomes simple and easy. It becomes clear at once that when the true position of a picture is known with reference to its station-point any number of direction lines from the station to points on the objects depicted can be ascertained with ease, because they will be the same as the direction lines from the station to the corresponding points on the picture. To fix the actual positions of the object points it is sufficient to know their several directions from a known point and the distances of those points along the direction lines. Generally it is not convenient or easy to determine directly the distance of a point along a radius of direction. The most convenient and best way for general purposes is to find the horizontal distance first, then the altitude, when the actual line or distance will be the hypothenuse of the right-angle triangle of which the horizontal distance and altitude are the sides containing the right angle. To find the horizontal distance a method of intersection similar to the plane table method of land surveying is used. Photographs of the same objects are taken from different stations. The direction rays to any point whose position is required are observed and projected on a ground plan, when the intersection of the projected rays will mark the position of the point on the ground plan. The altitude can then be ascertained by determining from the picture the angle of elevation and computing the height which would subtend the observed angle at a distance already ascertained on the ground plan. Also the altitude will be a fourth proportional to three lengths, which can be measured directly. These are (1) the distance from the station to the projection of the image point on the horizontal trace of the picture plane. (2) The horizontal distance of the point from the station measured in scale feet on the plan. (3) The measured height of the image of the point on the picture above or below the horizon.

Or it may be determined by substituting values in a general formula h=d tad n, where h is the altitude above or below the station, d is linear horizontal distance, a is the angle of elevation observed from the station and tan, and is $\frac{\sqrt{y^2}}{f^2+x^2}$, where f is focal distance and x and y are abscissæ measured from the centre on the horizon and principal vertical lines as rectangular co-ordinates.

* Summary of a paper read before the Society of Arts on April 16th, 1902.

In practice there are no considerable difficulties provided we have enough accurate information about the pictures which are used.

The methods so far considered and explained in outline relate only to the fixing of points on a ground plan by the methods of intersections and of elevation by the particular methods described. These methods are almost universally applicable, and with moderate care they yield very accurate results with much less expenditure of time, money and effort than would be needed for an ordinary survey of the same ground with a plane table or any of the other known methods of surveying. In Canada this method has been largely used, and it has been found that the actual money-saving from using the photographic method was then two-thirds of the computed cost of a plane table survey. A similar saving has been computed as the result of using this method for the survey of Trans-Balkal Railway in Siberia; and it seems reasonable to believe that with the improved instrumental appliances of the present time, and others perhaps to follow, the saving of expense for surveys hereafter will be from 80 to 90 or perhaps even 95 per cent. of the cost of similar surveys in the past by old-fashioned methods.

When dealing with buildings it is often possible for the photographer, without difficulty or much loss of time to measure directly with a tape the perpendicular distance from the diaphragm of his lens to the wall of the building to be photographed. This distance can be noted on the picture. This scale can then be calculated and constructed in a few minutes, and all distances on the surface elevation can be measured directly with a pair of compasses and that scale.

Distances on parallel surfaces nearer or further away, such as projections, porches, deep-set windows or other recesses, will require different scales of measurement according to their distances in advance of or behind the principal surface, or the same scale can be used for measurement and the results divided or multiplied by a constant computed for the difference. Another way to get the scale is to place a rod of known length in close contact with the surface where its image will be entirely included in the photograph.

Sometimes it is not convenient to walk up to a building to measure the distance to it or to place a measured length against it. A very efficient plan then is to shift the camera a measured distance to the right or left parallel to the face of the building, and take a second picture, when, if due care has been taken to set up the camera perfectly square in both instances, the images of the vertical hair on the face of the building will include between them a slice exactly as broad as the measured distance between the two camera stations.

One way to investigate flat surface areas is to apply what is known as the method of squares. If we imagine a plain area to be entirely made up of small squares, then the position of any point in the area is sufficiently determined if it is known in which square it is located and what is its position in the square. When dealing with a front view it is sufficient to superpose on the picture a sheet of glass on which has been ruled or photographed a network of regular squares in elevation. If the focal distance of the picture be known, it is a very simple matter to compute the scale value of the squares for different distances of the object surface.

Next in order of simplicity of measurement to a simple frontal view of a plane surface will be a horizontal surface or plan. For practical work regular series of perspective squares may be engraved or photographed on flat sheets of glass to make what are called perspectometers, which can be laid in position on the photographs with the scale surface next the picture face. These perspectometers need to be specially constructed with precise reference to the focal length of the lens in each case.

The method of squares which has been spoken of as applicable to the measurement and plotting of elevations and plans can be applied also for the measurement of other receding flat surfaces, such as the roofs or walls of buildings.

Sooner or later the time will come when photographic projection will be systematically employed for teaching perspective, and it will be employed practically, on a large scale, for projecting images from one plane to another. We must not expect to obtain full knowledge of unknown objects of three dimensions by aid of a single photograph, or even a number of photographs from a single point of view. To study unknown objects thoroughly we need to be able to examine them from several different points of view and compare the views. The use of photography does not obliterate this necessity, though it helps very decidedly towards correct final conclusions, because it records faithfully the appearance observed at every station, and these views from different stations can be brought close together and directly compared.

HOTEL DE CLUNY, PARIS.—(WOOD)

BY THE WAY.

The owners of flats in Chicago were recently proceeded against by the medical health officer at the instance of their tenants for refusing to supply heat until the first of May as per the terms of their leases. The courts gave the landlords the option of either heating their buildings or spending a term in gaol. The present coal famine, while bringing home to the owners of flats a sense of their burden of responsibility has tended to popularize life in a flat because of the lessened responsibility which attaches to this mode of living.

Frank W. Hoyt, editor of "Stone" in a letter recently addressed to the publishers of this journal says: "There is one point on which I wish to commend your Journal, which is one of the most interesting that comes into my office— you give a good deal of attention to stone. It is my experience that architects as a rule know comparatively little about the nature of the different kinds of stone. The various publications that represent their profession give most of their attention to the consideration of structural material to iron and steel. Unless there is some change in the future, I fear that we will rear a generation of architects incapable of undertaking any great masonry structures such as have dignified architecture in the past."

× × ×

When a man has built for himself a house to dwell in he ought to keep in mind not only his own ideas and requirements, but also the value which the building would be likely to have in the eyes of a probable purchaser. In this world of ups and downs the man who builds a house next year may find it necessary to sell it the year following or at some time in the future. This possibility should be kept in view from the outset. I could point you to a house built recently to meet the special requirements of the owner, but which is now on the market. It occupies a choice situation, but the value of the site as well as of the building has to a large extent been destroyed in the planning. Although expensively finished, the house does not contain more than two or three rooms of comfortable size, but is cut up into little boxes and narrow passages. If the owner should ultimately succeed in finding a buyer he will be obliged to sell at a heavy sacrifice.

× × ×

I am informed on apparently reliable authority that there exists in Toronto a plumbers' combine. Half a dozen of the leading firms are understood to be working together to secure the most important contracts at very profitable figures. I am told that when an important contract is to be let the members of these firms meet together and decide that it shall go to one or other of their number with the understanding that the firm getting the job will stand aside in favor of another member of the combination when other large contracts are given. I have been given to understand that the combine have in some instances forced up prices of heating contracts from 50 to 100 per cent. Every effort is made to prevent firms outside the ring from getting contracts, by throwing discredit on the quality of their work. Are the architects aware of the existence of this combine and of the fact that because it exists their clients are obliged to pay fancy prices for their work?

C. A. & B. STUDENTS' COMPETITION.

The publishers of the CANADIAN ARCHITECT AND BUILDER invite architectural students in Canada to submit designs in competition for a suburban or town house to cost not more than $2,500.

The building is to be designed for an inside lot having a frontage of 50 feet, situated on the west side of a street running north and south. The adjoining lots on either side have houses on them 30 feet back from the street line and 10 feet from lot line on either side.

Competitors are required to submit two elevations or a perspective, together with plans of basement, ground, first and attic stories, drawn to ⅛ scale in a manner to permit of reproduction within the limits of a double page of the CANADIAN ARCHITECT AND BUILDER, viz., 10x15 inches in size, also details to a larger scale of important or special features of the design. Drawings must be made with PEN and PERFECTLY BLACK INK on WHITE DRAWING PAPER, OR CARDBOARD. NO BRUSH WORK WILL BE ALLOWED.

Competitors should state the materials proposed to be employed in construction.

Drawings for this competition should be signed with a motto only and be accompanied by a sealed envelope bearing the same motto and enclosing the full name and address of the designer and the name and address of his principals. They should be sent FLAT by post or express, charge prepaid, addressed "CANADIAN ARCHITECT AND BUILDER, Toronto, Canada—Student's Competition," and must reach this office not later than noon on Saturday, January 10th, 1903.

The members of the joint Educational Committee of the Toronto Chapter of the Ontario Association of Architects and the Toronto Architectural Eighteen Club have kindly consented to judge the designs submitted in this competition, and their decision will be final.

The prizes offered are: First prize, cash $15.00; second prize, cash $10.00, third prize one year's subscription to the CANADIAN ARCHITECT AND BUILDER ARCHITECTS' EDITION.

The publishers of the CANADIAN ARCHITECT AND BUILDER reserve the right to publish any of the designs submitted and to withhold the prizes if in the judgment of the jury the designs should not be found worthy of the awards.

Intending competitors are requested to read carefully the conditions of competition, and to strictly comply with the same in every particular.

The Department of Public Works at Ottawa is said to have under consideration the installation of a system of pneumatic tubes for the speedy conveyance of communications between the various government buildings.

CHAMFER STOP (BUTTRESS), HEDON, YORKSHIRE.

BUILDING STONES OF NOVA SCOTIA.

From a paper read before the Nova Scotia Institute on the Nova Scotia minerals for the Paris and Glasgow Exhibitions, we abstract the following notes regarding the location, character and extent of the deposits of building stones in Nova Scotia. The quarries are in most instances conveniently situated for either railway or water transport and for effective quarry work. These notes refer to the quarries in the northern part of Cumberland County, which furnished samples of their products.

Quarries at River John.—No. 1. This is the only quarry at present working in this district. It is situated at River John and about a quarter of a mile from I. C. Railway, and is connected therewith by a good road.

It contains a reddish sandstone of fine grain, and has been opened for about 350 feet in length, exposing a face so far of about 14 feet. Stones are cut here up to about 33 cubic feet, though almost any size could be obtained with larger machinery. The seams are very regular in formation and lie nearly horizontal. Worked for nearly a year.

No. 2 adjoins the first quarry, and resembles it in general characteristics, though the stone is of a lighter color.

No. 3, about a quarter of a mile up the river from No. 1, was worked for six years intermittently. Many grindstones were cut in this quarry, which yields a firm gray sandstone.

Wallace Harbor.—The Wallace Gray Stone Co., Wallace Harbor, John Stevenson, manager. This quarry is situated at Wallace, and a great part of the stone is shipped by water, though it is connected with the I. C. Railway by a good waggon road about two miles long.

Though the stone is carried to the wharf by horses, a tramway (gravity) could easily be operated, the quarry being situated on the hill. The distance is about a quarter of a mile. This quarry has been worked for a period of nearly thirty years off and on, and is still only partially developed. It produces an average of about 1,500 tons ("quarry") a year, of fine grained sandstone in two colors—"olive" and "bluish."

Blocks up to ten tons in weight and measuring fourteen feet are cut, and the greater part of the stone is shipped to the Boston and New York markets. The poorer stone is sold locally.

Wallace Harbor.— The G. P. Sherwood Co., T. C. Dobson, manager. This quarry adjoins the quarry of the Wallace Gray Stone Co., and the same remarks apply to it.

At Wallace Bridge the famous Battye Quarry is being operated by George Battye. Stone has been taken from this quarry since the year 1809, and there is still much in sight. It is situated on the I. C. Railway and the Wallace River. Chief market, New York and Eastern States cities. Blocks up to ten tons are cut. At present 25 feet of rock is shown in the face, with seams measuring from two to six feet in thickness. This is composed of a very uniform and beautiful sandstone, suitable for monuments as well as construction work.

On the River Philip, about five miles from Pugwash, is situated the quarry of McLeod & Embree. It produces a handsome red sandstone contained in seams from two to seven feet, and shows altogether 20 feet in the face. Blocks cut to eight tons. Has been operated for upwards of 30 years, and usually ships to the States. This year all the stone quarried is being supplied to Toronto.

The Atlantic Stone Co., Limited, R. S. Hibbard, Manager.—The quarry of this company is situated on Cumberland Basin, 3½ miles from Joggins Station, on the Canada Coal Company's Railway, and 16 miles from I. C. Railway. The stone is shipped chiefly by water, in vessels up to about 300 tons. The market is mainly in the New England States, though the stones are occasionally sent much further west. 2,000 tons shipped per year. This quarry produces a very superior form of grindstone. Stones from half an inch to 14 inches thick, and up to seven feet in diameter are cut, though almost any size that could be handled is procurable.

At Lime Rock, West River, Pictou County, are sandstone quarries yielding good building stone. Samples are shown by Mr. J. H. Fraser. In the Merrigomish district the strata lying above the Productive measures yield grindstones and fair qualities of freestone.

Other localities are Pictou, and Glenfallock. On the Basin of Minas, Cornwallis, Johnston Brook, Horton, Falmouth, Kennetcook, Nine Mile River, and Old Barns, have yielded freestones in some cases of delicate shades and good texture. In Cape Breton sandstones from the Millstone grit and the Coal measures have been used to a limited extent for building purposes.

Syenites, Porphyries and Granites.—Granite is very abundant among the older rocks of the province. Among localities which have furnished it for building purposes, may be mentioned Shelburne, Queens and Lunenburg Counties. It also occurs at Aspotogan and various points thence to Halifax. As already mentioned, in describing the Gold fields, it runs continuously from Halifax to Windsor, and thence westward. It occurs again at Waverley, and runs through Musquodoboit, Jeddore, Ship Harbor, Sherbrooke, and Country Harbor to Canso. It occurs inland at the head waters of many of the Eastern rivers, and is estimated to cover a large area of the Atlantic coast district. It has, however, been quarried only at points accessible to shipping. At Halifax, it has been used a good deal about the fortifications, and a number of houses have been constructed of it, its cost, rough, being from $2.25 to $4.00 a ton.

In the Colequids there are masses of flesh and red colored syenite, which have afforded very handsome polished samples; but as yet have not been worked for construction. Porphyries and syenites occur in various parts of Cape Breton, but their economic value has not been tested. The following localities may be mentioned: St. Ann's, Boisdale and Coxheath. The crystalline diorites of Louisburg were used by the French in building their fortifications.

Limestones.—This material has not been used to any extent in Nova Scotia for building purposes, although it is frequently found to stand exposure well, and to be readily quarried. Among localities yielding it, may be mentioned the Shubenacadie River, Kennetcook, Lower Horton, Thompson Station; Glengarry and Springville, Pictou County. Stones from a quarry here retain, after an exposure of sixty years, every trace of the chisel or pick. The marble, will be noticed further on.

A flaggy, arenaceous schist, known as iron stone, was extensively used some years ago for warehouses and walls in Halifax. Many of the metamorphic sandstones of the Atlantic coast would furnish a most pleasing and durable building material.

At present the supply of wood for building purposes is so plentiful that brick or stone houses are the exception. Even public buildings, churches, halls, etc., are almost always of wood ; but as this material becomes more expensive, the labor of the quarryman will succeed that of the lumbermen, and our towns become something better than wooded shells blackened by smoke.

Flags and Slates.—A small amount of flagstone has been quarried on the Northwest Arm of Halifax Harbor, and at Beaver Bank. Slates were quarried to a small extent at Rawdon, and various places in Hants County, and the quality and quantity are equal to any demand. Dalhousie Mountain and West River, Pictou, are said to have good slate beds, and it is also reported from the South Mountain, in Digby and Yarmouth Counties.

At the Provincial Exhibition of 1879, slates were shown from Sackville, River John and Upper Stewiacke, which, although in the rough, were of good material.

The demand for roofing slates will become general in the province in a few years, as their superiority over the shingles in ordinary use becomes apparent.

In Nova Scotia the limestones are confined practically to the Lower Carboniferous, and are generally associated with the gypsums. There are also beds of this material, sometimes metamorphosed into marble, in the Laurentian, etc., of Cape Breton, and in the Cambrian and Silurian measures, but they do not usually form deposits of economic value in the latter measures. The carboniferous limestones are strongly developed in Cumberland, Colchester, Hants, Kings, Pictou and Antigonish Counties, and at many points in Cape Breton. They occur in beds varying in thickness from a few inches to 50 feet, and in some localities their aggregate dimensions will exceed 400 feet. Their quality varies from calcareous sandstones and clays to the crystalline pure mineral.

At Windsor, Brookfield and many other localities beds are found composed entirely of fossils characterizing the Marine Limestone formation, and give the following component parts on analysis by Dr. How :

Carbonate of lime	97.64
Carbonate of magnesia	1.10
Oxide of iron	.07
Phosphoric acid	trace
Insoluble residue	.68

A limestone similar to the above was extensively quarried at Brookfield as a flux for the Londonderry iron ores.

The limestones of Pictou County are also well adapted for fluxes. The following analyses of a limestone from Lime Brook, Springville, were made for the Halifax Company at the Durham College of Physical Science :

	I.	II.
Lime carbonate	93.90	96.26
Magnesia carbonate	2.45	2.33
Iron peroxide	.59	.57
Manganese peroxide	.56	.55
Alumina	.12	.10
Sulphur	.03	.02
Phosphoric acid	.03	.03
Silica	2.10	1.99
Moisture	.18	.17

These results are confirmed by an extensive series of analyses made some years ago by the writer, embracing all the more important exposures of that mineral in the vicinity of the Pictou coal and iron deposits, but the space at my disposal would forbid its insertion. The position of the East river limestones forms an important item in their adaptability for fluxing purposes.

They occur as a band everywhere between the coal and iron, so that their transport becomes a matter of comparatively low cost, and large quantities are available by simple quarry work. A quarry at Black Rock, above Bridgeville on the East Branch, has furnished flux for many years to the Ferrona furnace.

THE ELECTRIC ELEVATOR.

Mr. Douglas, manager for Canada of the Otis Elevator Co., recently addressed the members of the Toronto Chapter of Architects on the development of the electric elevator. The first electric elevator was made in 1881, and strange to say the original principle of construction is still employed. Between 1881 and 1888 when the electric elevator became a commercial success, it suffered many vicissitudes. Its popularity is however now assured, and the modern electric elevator can be depended on to operate satisfactorily day in and day out, at any desired speed from 150 to 500 feet per minute. Many improvements have been made in the device, such as placing the operating mechanism at the top instead of the bottom of the shaft, thus securing economy of space. Elevators are now frequently installed in the more costly residences, and are fitted with antomatic appliances which render accidents almost impossible. For example the door will not open except when the elevator is within two inches below or above the floor. These elevators are fitted with a push button, corresponding in number to each of the several floors, and the elevator responds in the order in which the signals are given.

The Ministerial Association of Toronto have given their partial approval to Alderman Graham's scheme for improved dwellings for the poor, but wisely suggest that such dwellings should be located in the suburbs rather than in the heart of the city.

The death is announced of Mr. Peter James Murray, a prominent and highly respected contractor of Montreal.

The Canadian Fire-Underwriters' Association have decided to impose a special rate of insurance upon buildings in which are housed automobiles operated by gasoline.

We record with much regret the death of Mr. Wm. A. White, architect, of Lindsay, Ont. While superintending the building of the new hospital in that town he contracted a severe cold which developed into pneumonia and resulted in his death. Deceased had resided in Lindsay for 35 years, and during this period erected many important buildings. He was held in universal esteem.

BUSINESS NOTES.

Adams Automatic Self-Locking Sash Lock has been pronounced by architects and builders a most valuable invention.

The Art Metropole, Yonge street, Toronto, are about going into the manufacture and supply of arcbitects' materials extensively.

Palmer's Patent Hollow Concrete Building Blocks will soon be extensively manufactured in Canada. We hope to give further particulars next month.

The Canadian Construction Co., of Toronto, are preparing to go into the structural and contracting work on a very extensive scale. Their announcement will appear in next month's issue.

The Patent Interlocking Rubber Tiling made by the Gutta Percha & Rubber Mfg. Co., of Toronto, Ltd., has proven a success. Their new announcement will appear in next month's issue.

The York Manufacturing Co. was established four years ago for the purpose of manufacturing in Canada a full line of laundry machinery, with the following gentlemen as officers:—Messrs. J. M. Spencer, president; H. G. Macklem, secretary-treasurer; W. Hawke and A. J. Spencer, directors. Mr. Spencer is a prominent citizen of Toronto, whilst Mr. Macklem has been engaged in various manufacturing enterprises for 27 years. Mr. Hawke is also a well-known Toronto business man. Mr. A. J. Spencer is town treasurer of Owen Sound. They are now manufacturing a full line of machinery for modern steam laundry business. They instal complete plants, furnish plans and estimates for public laundries, hotels, public institutions, hospitals, etc.

the north and west, the multiplication of industries in which cement is employed and the many new uses to which the material is being applied, there is no doubt still room for a considerable development of the industry. After the home demand shall have been met there will remain foreign markets to be exploited. There is no reason why Canadian cement manufacturers should not be successful in securing their share of foreign orders, as manufacturers in other lines are doing. The demand for cement is said to be rapidly increasing in the Spanish-American countries, as the result of the inauguration of extensive public works. No cement is manufactured in these countries, 95 per cent. of the demand being supplied by Hamburg and the remaining 5 per cent. from England. The French Commercial Adviser recently suggested that a group of French manufacturers of cement and mosaic tiles should form a syndicate and appoint five energetic representatives, who speak Spanish and are acquainted with the customs of the countries. They should be supplied with samples and visit the principal Latin-American towns with the object of obtaining government and municipal contracts. These representatives should be apportioned, as follows :—1. Mexico and Central America, Cuba and Porto Rico. 2. Venezuela, Colombia, Guiana and the lesser Antilles. 4. Argentina and Uruguay. 5. Brazil and Paraguay.

OUR BRITISH TRADE SUPPLEMENT.

A new feature appears in this number, in the form of a British Trade Supplement containing the announcements of a number of representative British firms engaged in the manufacture and sale of various materials for the use of architects and contractors. These British firms desire to introduce their goods in Canada, under the terms of the preferential tariff, and to obtain competent and reliable persons to act as their representatives in this country. The well-known reliability of British manufactured goods, and the desirability of closer trade relations with the mother country, should prompt Canadian architects and contractors to carefully examine the announcements appearing in our British Trade Supplement, to open correspondence with the various firms represented therein, and make fair trial of the goods offered. The publishers of the CANADIAN ARCHITECT AND BUILDER will be pleased to supply from their offices in Toronto and Montreal catalogues and information in behalf of these enterprising British firms.

C. A. & B. STUDENTS COMPETITION.

Thirteen sets of drawings have been received in our Students' Competition for designs for a $2,500 Town or Suburban House. The drawings are now in the hands of the Committee of Award representing the Ontario Association of Architects and the Toronto Architectural Eighteen Club. On account of the annual convention of the former and the annual exhibition of the latter in progress at present, it was found impossible to have the designs considered in time for the result to be announced in this number. The Committee's report, with perhaps one or more of the successful designs, will be published in February. Meanwhile we wish to express our appreciation of the manner in which the Students have responded to our invitation to enter this Competition. It will encourage us to announce others from time to time in the future.

ARCHITECTURAL LEAGUE EXHIBITION.

The Eighteen Club's display of photographs and prints, which constitute the circuit exhibition of the Architectural League of America, is of moderate interest. The most satisfactory work shown is in the collection of prints of English work, which are however very small and usually show no more than a distant perspective view of the parish churches which they represent. As English work, following English tradition, and suiting English taste and English church worship, these are admirable. An old English church or a modern English church may be, and are, of the same family, and the one seems as appropriate as the other: Mr. Cram, whose opinion given in his lecture before the Eighteen Club at the gallery on Jan. 17th, was courageously in favor of the same church design for the same form of worship in the Protestant Episcopal Church of America, is represented on the walls of the exhibition by a photograph of the well known drawing of his perpendicular church at Cohasset, Mass., but there is no getting over the feeling that this is an imitation, an English importation, planted on foreign soil. Whether this sentiment is reasonable or not, it is strong, and it is such sentiment that influences, or ought to influence the character of architecture, so as to bring it into the necessary harmony with its environment. It is safe therefore to say that the style of church design, which seems good on English soil and does not seem good on American, is good in England and is not in the United States.

The most interesting exhibit is without doubt the French work. French logic goes on where we only speculate, and the Frenchman becomes either a noble example or a shocking one. Even when he becomes a shocking example one cannot but admire the nobility of the spirit that led him to it. As a matter of fact the steel church, which is the text of these remarks (an uncompromising erection in unprotected columns of steel beams, rivetted together, and arched trusses of steel angle bars) bears study well and even grows a little upon the affections by study. It would at any rate inspire respect if not love, while a Chicago architect's church, which is shown both in its steel skeleton and again as a barrel vaulted structure; with coffers, vaulting ribs, arched recesses, and all the rest of it; excites nothing but loathing and boredom. It is dull.

The great interest of the exhibition, is Mr. Challener's decoration for the ceiling of the steamer Montreal, which forms part of the exhibition because Mr. Challener is using the gallery as a studio for this large painting. People who are accustomed to regard pastels as a convenient medium for amateurs, because it lends itself to a fuzzy effect that peculiarly suits a wuzzy manner of execution, should look at Mr. Challener's pastel studies and see that the real forte of pastels is a luminous brightness. The painting from these studies loses nothing in color. The ceiling will be a real work of art. The masses of floating figures—floating between dawn and darkness—form a decorative motive running through the two panels continuously, so as to carry on the idea which is represented by both together. And the figures do float: they form a large composition, are combined in interesting groups and are beautifully modelled, but they float like the irresponsible figures of a dream.

INTERCOMMUNICATION.

[Communications sent to this department must be addressed to the editor with the name and address of the sender attached not necessarily for publication. The editor does not hold himself responsible for the expressions or opinions of correspondents, but will, nevertheless, endeavor to secure correct replies to queries sent in. We do not guarantee answers to all queries neither do we undertake to answer questions in issue following their appearance.]

"H. R.," Fullarton, Ont., writes: You will greatly oblige me by answering the following questions through your paper. (1) Is cement a good thing to put with mortar used for plastering a smoke flue? I have heard cement will not stand fire; is this a fact? (2) What is good to mix with mortar (to be used for plastering a smoke flue), to give a glossy face? (3) Will mortar stain act as a good colouring for cement work?

In answer to the forgoing it may be said, (1) That putting cement in mortar for paving or plastering the inside of a flue, has no special advantages over plastering with well made lime mortor. (2) Cement, under ordinary circumstances will stand heat as well as, all lime mortar. (3) A flue can be made smooth inside by using good lime mortar, and then "trowelling" it well, or floating it until it is quite smooth. Our old fashioned method—and a good one—was to mix cow dung with the mortar and working the whole up into a thick paste and parying the flue with the maise. Flues treated in this manner keep a smooth surface inside for many years. Where fire clay is abundant it is a good plan to coat the flues with it, as it stands heat and remains smooth. One of the best flues is formed by using common glazed drain tiles for the smoke duct, which are built in the chimney. The brick flue, is of course left square inside, and the tiles are cemented at the joints as the work progresses. The angles or voids left, may be used with effect for ventilation purposes. Mortar colors will answer fairly well for the coloring of cements. Any of the mineral colors will answer the purpose, but, in all cases, the introduction of coloring matter, depreciates the strength and durability of the finished cement work.

From "Draftsman" : In answering my "query" in the October (1902) number of THE CANADIAN ARCHITECT AND BUILDER, you say : "Scale drawings can be reduced by the use of a pantograph." Will you please describe a "pantograph," and tell how to use the instrument?

ANS :—The following, which is taken from "Hodson's Universal Carpenter and Joiner," gives the best description of a pantograph, and the manner of using it, that we can lay hands on at this moment : "By reference to the engraving, Fig. 1, it will be seen that the instrument consists of four parts, resembling rulers jointed together at their extremities, and two sliding carriages, having provision on their under sides for holding a pencil, while they are provided with clamping screws to hold them in their places.

The pieces AB and AC are each two feet four inches long, from the centre of the screw at A, to the extreme end, one-inch wide and one-quarter inch thick. The distances centre AD, AE, FD, FE, are equal, being twelve and a half inches. All the joints of the instrument are made with one-inch screws, and small blocks of hardwood, one-inch by one-inch, by half-inch thick, are glued under each joint to form a good hold for the screws. It is scarcely necessary to say that all these screws should be filed or turned perfectly smooth and round, the ordinary wood-screws being too rough and irregular. The fulcrum B is a leaden weight four inches in diameter, and about one-inch thick, having a wooden stem in it, so that it measures two and a quarter inches from the underside of the lead to the top of the wooden stem. A stout needle or short piece of wire, is driven into the top of the stem for the instrument to turn on. The holes in the piece AB at B, are about half an inch apart, and of such a size as to slip over the wire on the fulcrum easily. The pencil used must be rather a hard one and must be nicely pointed by a file or a piece of sand-paper.

The sliding carriages G and C are made of two pieces of black-walnut or other suitable wood, 2"x1¼" x⅛" thick, and two pieces ½"x¼"x1¼" long; the small pieces are glued between the ends of the large pieces so as to make a block, with a hole 1"x¼" (the size of the rulers) running through it. The pieces AC and DF must now be slightly reduced so as to slide easily, but not too freely, through the holes in the carriages. Two ordinary thread spools with one end of each sawed off square, just where the level ends and the straight part on which the thread is wound, commences. One o

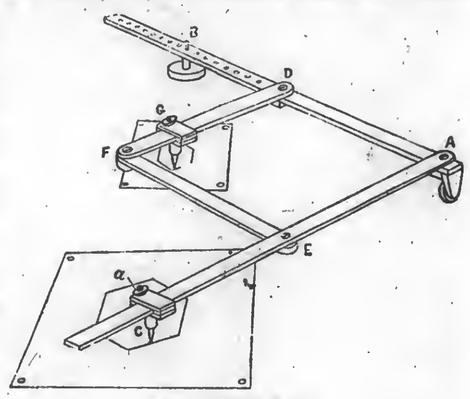

FIG. 1.—PANTAGRAPH.

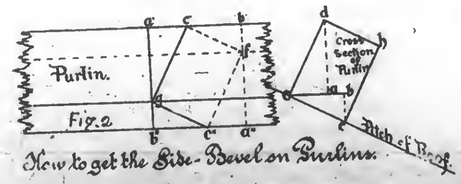
these spools must now be glued to the centre of one of the thin sides of each carriage, and the opposite side must be cut through one of the joints where it is glued to the ⅛"x¼"x1¼" piece, with a thin saw, so that when that end is pinched together it will bind on the ruler, where before it slid easily. The clamping screw is made of a common 1-inch wood-screw, inserted from the side on which the spool is glued, and the head countersunk, in the centre of the width of the carriage, and ¼ inche from the end, thus passing through the middle of the joint that was cut. To prevent the screw from turning and also from dropping out a small wire staple similar to a double-pointed carpet tack, is driven across the head of the screw so as to lie in the groove, and a nut is made from a piece of hardwood one inch long by half an inch wide and three-eights thick, cut to an oval shape and slightly rounded on the underside, so as to bind only on the bottom as shown at A. In order to get a good clean thread in the nut, a tap may be made by taking a common screw of the size you are using, and with a saw-file making three or four grooves lengthwise of the thread deepest at the point. To reduce a drawing to one-half of the original, set the instrument so that a hole at B, which is in line with the points of the

pencil at C and G is just as far from G as that point is from C. The pencils should fit tight in the spools by wrapping paper around them; a screw may be inserted to hold them, but it is not necessary. In setting the instrument it is always necessary to have the pencils and the hole in which the fulcrum is placed perfectly in line. For this purpose a piece of wood the size of an ordinary lead pencil about four inches long, with a knitting needle driven into the end, so as to be in line with its centre, is very useful, as by placing it in the carriage at C, and then sighting across the point of the pencil at G to the point in B, they may be adjusted perfectly in line. The distance from B to C represents the original, from B to G the reduced copy; by varying either any amount of reduction may be made. Instead of two pencils a piece of hardwood the size of a pencil, made sharp at the point may be used with advantage at C, when reducing, and in G when enlarging. At A, on the underside of the piece A B, and just beyond the block under the screw, is glued another block 2 1-8 inches long, of the form shown, and at its lower extremity is fastened by a screw, a small wheel, readily made out of a coat button and projecting below the bottom of the block to which it is fastened one-eighth of an inch. When passing from point to point of the original and not wishing to make a mark on the copy, the pencil may be raised from the paper by raising the point at F a sufficient height. The method of using the instrument is very simple. If you wish to enlarge a drawing you place it under G and move the pencil or tracing point along its lines. New lines will then be traced by the pencil at G, and the drawing at C. Trace the drawing and the point G will define a reduced copy." There are several styles of this instrument but the principle in them all is the same. Every dealer in mathematical instruments keeps them for sale and the price varies from fifty cents to ten dollars. One good enough for ordinary purposes can be bought for about $2. Any clever carpenter can make one if he follows the directions given in the foregoing.

From "Carpenter": I am building a good sized stable and barn combined, and rafters are 28 feet long and I am obliged to put a purlin under them about half way up, and as the roof is "hipped," it will require to have the purlins mitred at the angles. How can I find the lines on the timber to cut this mitred joint?



ANS.—See Fig. 2 and follow the directions below and you will get the lines desired. Draw C E equal to the pitch of the roof, draw C D perpendicular to C E, and C D, H E equal to a section of the purlin. From D and E draw D A and E B vertical, and from C draw C B horizontal. Now take your purlin and square over two sides as A' B". Make A' C' equal to C A and B" C" equal to C B; connect C' G and C" G. This will give the cuts on the bottom and inside sides. The cuts on top and outside sides may either be obtained with a bevel, as they have the same bevel on opposite sides, or make C' B' equal C B, and C" A" equal C A, from B" and A" square over to F, and connect as shown. The dotted lines are supposed to be on the opposite side of the purlin. This will give the mitre for all equal and different pitches if the building is a rectangular one.

From "Cautious": Is it better to use a single timber for a girder or bressumner, than to make one or other of built up timbers?

ANS: Wherever possible, solid timber should be used. Built-up timber—that is timbers which are formed of a number of flat short pieces spiked, bolted or screwed together. In long stretches perhaps built up timbers may have some advantage, as the whole length of timber can be so constructed as to seem all in one length.

From "Stonecutter": Will you kindly describe (and illustrate) the proper method of laying out a segmental arch and oblige?

ANS: If our correspondent will carefully follow the

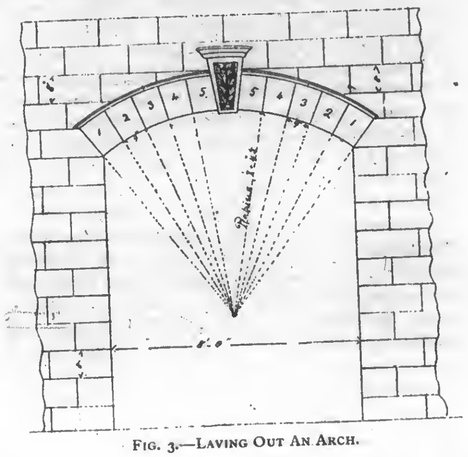


FIG. 3.—LAVING OUT AN ARCH.

sketch,—Fig. 3,—given herewith, he will see how all joints are made or set out. He must also see how the pocket pieces over the arch stones 4 and 5 are made. The lines for the bevels of the stones are obtained from the common centre O, the dotted lines showing the direction of the bevels. Care must be taken to free the the key-stone from the blocks above so as to equally distribute the weight and pressure.

TORONTO BUILDERS' EXCHANGE.

According to the reports presented at the annual meeting held on the 19th inst. the Exchange has enjoyed a prosperous year. the following officers were elected for 1903:—President, Joseph Russell; First Vice-President, R. G. Kirby; Second Vice-President, John Hoidge; Treasurer, David Williams; directors, Messrs. Nelson, Weller, Crang, Martin and Smallwood; Auditors, Messrs. Clay and Holmes; Representative on Technical School Board, J. M. Gander; Representative on Exhibition Board. J. B. Thomson.

The Industrial Publication Co., of New York, have recently issued a second edition of 100 cloth bound pages of Fred. T. Hodgson's book "The Hardwood Finisher," containing rules for preparing wood work for the finisher and for finishing hardwoods, as well as pine and other domestic woods. The price of the book is one dollar.

MODERN CONSTRUCTIVE METHODS.*

Had I seen Mr. Pearsons remarks delivered at your annual meeting of 1902 before accepting your Registrar's very kind invitation to read a paper at this meeting I greatly fear I would have refused.

At the best it is very embarrassing to a modest engineer, and modesty is the essential characteristic of the engineer, to appear before such a body of men as this. It becomes doubly so, when they have been informed in advance that he belongs to a 'clique who are using all their wiles and blandishments to seduce the simple-minded and unsuspecting architect into all kinds of nefarious schemes and awful projects.

Mr. Pearson's description reminds you of the Garden of Eden with the poor engineer in the role of the wise and subtle serpent, and the architect, whom I have always found perfectly able to take care of himself, under any and all circumstances, personating the lovely, but misguided Eve. However, I thank Mr. Pearson for one remark. He says: "For the solution of these problems it was necessary to appeal to the engineer." And he was right. In these strenuous days an Admirable Crichton, or a Lionardo Da Vinci becomes an impossibility. Competition is too keen; the lines are drawn too closely.

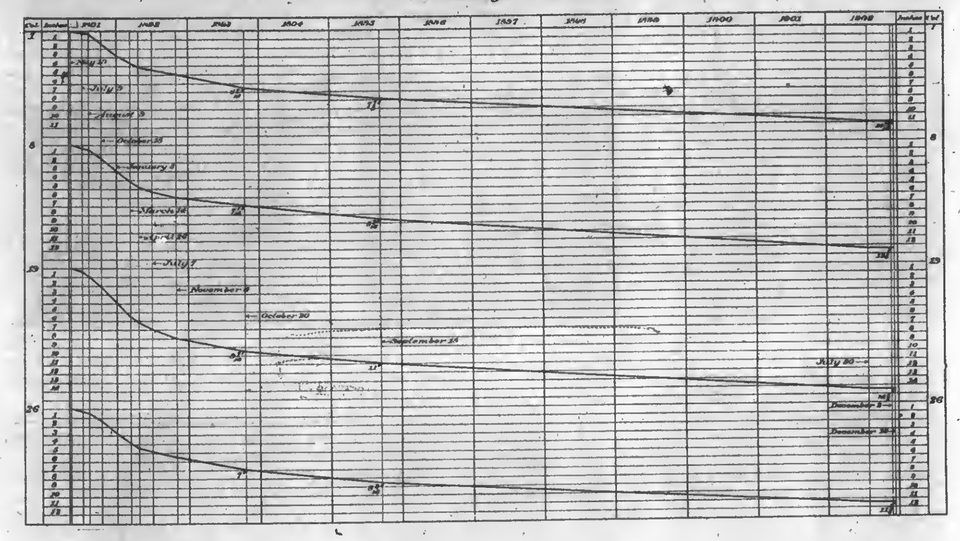
It is not many years ago that the architect felt himself to be, and was, perfectly competent to do any class of work which came to him. Now when he is designing a large office building, or any similar work he not only has to call upon the structural engineer, but the electrical, the mechanical, the sanitary, the heating and ventilating engineers as well.

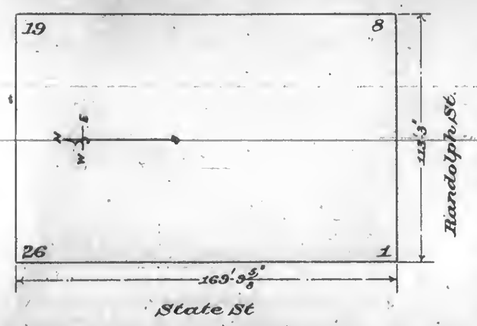
The architect is at the head, he is responsible for the completed structure, and the designs of the various engineers are only integral parts of the whole, but it is manifestly impossible for one man to know all of the details of the various lines. He may have a smattering of each, but he cannot know, he has not the time to master each and every one. When he tries to do so he fails.

After this somewhat lengthy preamble I will get into the subject matter of my paper.

The most interesting portion of a building to the structural engineer is the foundation.

Levels Showing Settlement of Masonic Temple Chicago.





In Chicago the very compressible soil made unusual care necessary in designing the foundations of the high office buildings.

The soil of Chicago is made ground to a depth of 12 to 14 feet thick, then a layer of hard clay 6 to 10 feet is struck, and upon this layer is placed the spread foundations. Below this layer is a soft clay extending down to a shale formation overlaying the rock, the latter being found at a depth of 80 to 100 feet.

The first high buildings were put on spread, or floating foundations made of steel beams imbedded in concrete. Each foundation was made of such a size that the load coming on the clay would not exceed 3,000 to 3,500 pounds per square foot. This often necessitated putting two or more columns on one foundation.

In figuring load on clay, only dead weight of building is taken into account, as it was found impossible to get a uniform settlement when live load was carried into the footings.

In one large and costly building in Chicago built some years ago after plans by a celebrated Boston architect, the live load was considered in designing the foundations.

The result is that the walls of the building settled very much more than the foundations, carrying the interior columns, and the floors are 6 or 8 inches higher at the center than around the outside. In consequence extra men are stationed on the floors to help the truckmen push the trucks up the incline.

The settlement of the buildings put on spread foundations is from 8 to 20 inches. This is allowed for by putting up the foundations when work is begun.

*Paper read at the annual convention of the Ontario Association of Architects held in Toronto January 13th and 14th, 1903.

The settlement curves of the Masonic Temple 300 ft. high are shown on preceding page.

The first vertical row of figures on the left give the number of the column, the next row the inches of settlement, and the other spaces on the right show the years covered by the observations. You will note that the settlement is not great for about 2 months after foundations were put in place, but as the building went up, and the loads on the footings increased the curve becomes very much sharper. You will also note that the greatest variation in the settlement of the columns occurred at the start when the difference in loads was greater, afterwards the settlement becomes almost uniform, changing at north-east corner when the smoke stack at column 19 was increased in height, causing an increased settlement at this point.

No settlement has taken place in the past 5 months as shown by the horizontal lines. It is, however, questionable whether any of the very high buildings ever entirely stop settling owing to the effect of the wind against them. The prevailing winds in Chicago come from the west and south-west, and the higher buildings when they lean at all, invariably lean east.

The Great Northern theater hotel and office building was erected east of the Great Northern Hotel built several years before. The hotel has a court in the center of the east side, and the theater of the new building adjoining the court on the west.

Heavy fire walls separate it from the office and hotel portions. These walls, each weighing, with the floor loads, 60,000 pounds per lineal foot, meet the east wall of the present Great Northern hotel at right angles. This east wall had been originally designed as a party wall, and its footing had been constructed strong enough to carry a floor load from each side. The end of the theater wall, where it meets the east wall could not rest on the footing of the latter, which projects 9 feet 6 inches, as it would overload the footing, being only on one side, besides being too great a load. The old building had also practically stopped settling, and the new one would probably settle 10 to 12 inches. The floor load, however, from the east side had never been put upon this footing, and in addition it was deemed safe to load it somewhat higher than it had been originally, as the east wall, fourteen storeys high, had been resting upon it for four years. Plate girders were placed lengthwise in the theater wall, with their ends projecting through the old wall, and resting on 36 ton hydraulic jack-screws, which in turn were supported by I beams lying on the footing and parallel to the old wall. The plate girders were of such a length and so located as to transfer to the old footing the desired weight. The screws were raised to their full height, so that they could be lowered 14 inches if necessary. As the new building settled these screws were run down at regular intervals until the settlement stopped. Levels are being taken on the building. After the settlement has entirely ceased the screws will be surrounded with concrete and left.

A rather curious example of foundation exists at Duluth. The Duluth General Electric Company very recently installed a 1,000 k.w. dynamo, and the vibration caused by it affected buildings 500 feet away. The vibration of a 5 storey building over 500 feet away was very perceptible. The building is close to the bay, and I found on examination that the ground is swamp and made ground, down to about 16 feet, where a hard strata is found. This made ground is filled with water and transmits vibrations in waves.

The buildings are built on piles driven into the hard ground, but the top 16 feet are entirely unsupported laterally. One building, however, also about 500 feet away, was found to have no vibration whatever, and it developed that when the foundations of this building were put in the whole area was excavated down to the hard ground and filled with sand to the top of the ground.

In order to avoid the excessive and long continued settlement due to spread foundations, piles were used, and latterly concrete caissons going down to the shale overlaying the rock, or going down to the rock itself are supplanting both. When it is not found feasible to go clear to the rock the caissons are belled out at the bottom, generally to twice the diameter of the caisson itself: that is a 6' caisson is belled out to a diameter of 12 feet on the bottom and the angle of the slope of the bell is about 30 degrees with the vertical. Where the caissons go to rock the belling is not necessary. The caissons are made by digging down from 4 to 6 feet, just as a well is dug, and then lining up the shaft with wooden lagging, the strips vertical, held in place by iron hoops made adjustable. Then another section is excavated and lagging put in, and so on down. When bottom is reached concrete is put in, and lagging removed one section at a time until hole is filled.

One building now being erected will rest on about 90 caissons from 7 to 10 feet in diameter, carried down to rock which is from 100 to 104 feet below surface of ground.

A large State Street department store now occupying a 6-storey building, has just started to tear down the old building, and erect a 16-storey building in its place. The foundations for the new building, however, are all now in place, and have been put in during the past three months. Over 60 concrete caissons from 60 to 80 feet deep have been built without disturbing the old building, and without the knowledge of the thousands of shoppers who daily filled all the floors above. In some cases it was necessary to shore up the old building, and take out an old basement pier and put a caisson directly under it. At night the material excavated during the day was taken up to the street through an opening in the sidewalk, and hauled away in wagons.

Concrete caissons and piles are often used in foundations of some buildings.

There is no settlement when caissons are used beyond that due to the shrinkage of the material while being put in place.

The use of concrete either in large masses, or reinforced by steel has made great strides in the past few years and continues to grow in favor.

The drainage canal used it in immense quantities and in some cases in a very bold manner.

These two views show a recent concrete structure, for the Economy Light & Power Company at Joliet, Illinois.

The next (not shown) shows steel cylinders filled with concrete. These cylinders are 7 feet in diameter, 52 feet high above the masonry and carry the ends of two 380 feet spans. The masonry piers are only stone on the outside, the stone being 24 to 30 inches thick, and the interior is concrete.

I have here three samples of concrete. Numbers 1 and 2 were taken from foundations of the L.S. & M.S. & C.R.I. & P.R.R.'s at Van Buren Streets which were put in about 31 years ago.

Sample No. 3 is about 8 months old, and is taken from the foundations of the new station now being erected.

The old station was built with limestone walls. When the building was torn down this limestone was put through a crusher, and the concrete of which this sample is made is from the limestone just as it came from the crusher without screening.

FIREPROOFING OF STEEL FRAME.

After foundations, next in importance comes the fireproofing of the steel frame of the building.

Concrete floor systems are now being exploited in great variety.

Some of the systems have merit, but all of them make too great claims.

A concrete slab 3 to 4 inches thick, even if reinforced with steel in some form or other, should not be used in a very much greater span than we now use for steel beams with hollow tile arches between. It has beengrtavely told me by a concrete sales agent that in case of fwo 15 in. beams, say 7 ft. span it would be perfectly sae not only to deduct the difference in weight of floor between the 3 in. concrete slab they proposed to use, and the weight of a 15 in. hollow tile arch, but in addition the section can be reduced 25 per cent. on

Oct. 12th, 1895.

Oct. 19th, 1895.

Oct. 26th, 1895.

Nov. 12th, 1895.

Dec. 12th, 1895.

April 29th, 1896.

account of the help the concrete gives the steel. In other cases they state you can, with concrete, use 17 to 25 foot spans, and save all the steel thereby taken out.

One question, however, they decline to answer. Ask them instead of telling the vertical load it will support without collapsing to turn their slab of concrete 3 in. or 4 in. thick and 17 ft. to 25 ft., span, on edge, and then load it. They invariably decline to test it this way. Now in a 20 or 30 story office building, lateral stiffness in the floors is more essential than carrying capacity. A thin slab of concrete laid on top of 12 or 15 beams cannot by the very nature of things, add to the lateral support of these beams. But a 12 in. or 15 in. hollow tile arch laid in between the beams does make a stiff floor.

Experiments as yet have not demonstrated that concrete floors are fireproof as compared with hollow tile which already has been burned.

While I have faith in concrete and believe it has great possibilities which will be demonstrated in the future, yet I think that now, in order to compete with hollow tile, its advocates are making claims which cannot be substantiated, and in the future they will have to be more conservative not only in their statements, but in their construction in order to succeed.

Recent failures in Jackson, Michigan, where the falling of the floors pulled down the outside walls; and of four floors which collapsed in a $500,000 apartment building in Chicago will undoubtedly prove beneficial in the lessons they teach. Many other failures in concrete floor construction have occurred in the past few years, but these are the most recent.

Another thing, a building is not necessarily fireproof because it has steel floor beams and columns. Naked steel or cast iron is not fireproof. Wood is far preferable, for if it is of sufficient size it chars on the outside, and the charring acts as a protection. Every bit of structural steel must be covered with a fire-resisting material in order to be fireproof.

The last engineering papers give an account of destruction by fire of two English spinning mills, one resulting in the death of nine persons, injury of a large number. The report sums up both disasters as due to the breaking of the cast iron posts, but the same report says the cast iron posts were left bare. In the absence of further information it is only reasonable to suppose that the true cause is that these columns were not fireproofed.

Another and possibly a greater danger than fire is rust. Examination of steel buildings made recently show that the danger is not as great as some alarmists would have us believe, yet it exists.

In a building built in Buffalo in 1895 all the outside columns were filled with cement grout after the brick and fireproofing had been put around them, thus making the whole pier solid monolith with steel core. This

s now being generally followed in the best buildings. While the interior columns do not need this treatment, it is well to fill around them solidly at every floor, because if it does nothing else it will prevent rats and other vermin going from one floor to another. Floor loads: The building ordinances of the different cities cover all cases so completely, that very little is to be said. New York and Chicago both demand 100 pounds per square foot for each floor of an office building, or one to accommodate public gatherings.

WIND BRACING.

A great deal has been written about wind bracing in high buildings, and a great many methods of taking care of wind pressure have been brought forward.

Diagonal rods and portal bracing have been tried, but but interfere too much with floor space, and the former especially can not be carried out and made a perfect system.

In the Fisher building Chicago erected in 1894, the wind was taken care of on the table leg principle. Around the outside of the building at every floor the spandrel sections were made of plate girders 30 inches deep run between the columns and riveted to them. Each floor was supposed to transmit pressure to all the columns of the building in that story, and so on to the ground.

TIME OF CONSTRUCTION.

The views shown on preceding page of the Fisher building show the time in which a steel building can be erected.

DISCUSSION.

Mr. Shankland: These curves shew the settlement of the Masonic Temple in Chicago from 1891 till about two weeks ago, on December 15th. The figures on the left are the numbers of the columns at each corner of the building shown on this sheet. The building is twenty stories in height. You will notice the curves are quite easy for the first few months of construction. The zero was taken at the first construction. As the building becomes older the curves become very much sharper and the greatest portion of the settlement had taken place at the time the building was finished. The first shew the dates from 1895 to 1897; the settlement was almost exactly uniform. Then they put extra weight on corner No. 19; they ran the stack up higher; and you see, in the increased curves there, that the founda ion was affected at once. The settlement was 10 5-16 inches, 12⅞ inches, 14½ inches, 11 9-16 inches. The greatest settlement is 14½ inches; the least of those four corners is 10 15-16 inches. The foundation was on spread footings, the load was 3,200 pounds dead load.

A Member: How much of that settlement is live load responsible for.

Mr. Shankland: I do not think the live load causes any additional settlement. I do not believe a building of that size in Chicago ever stops settling; I believe the wind pressure has enough effect to keep a small settlement.

A Member: In that case inside columns would not be affected by the wind.

Mr. Shankland: The building acts as a monolith in that way. From July to December last there is no settlement shown. The levels were taken then. But that is too short a time to place any dependence on. This next photograph shows a work of solid concrete, twenty-six feet high and from six to eight feet on top. This is the Economy Lighting & Power Company of Joliette which is using drainage water to generate power to send to Chicago. That concrete work is not reinforced at all. It is a solid mass of concrete. The next photograph is shewn to illustrate the way concrete is used in bridge piers; those cylinders are seven feet in diameter and fifty-two feet high filled with concrete; the masonry is above high water but it is only a shell of masonry and the interior is all cement concrete. Those piers are 62 feet long and 22 feet high. The concrete is figured to carry the load and the steel only acts as wind bracing.

A Member: Why was not concrete used for the foundations.

Mr. Shankland: It would have been better if they had concrete instead of the natural stone, but the Board of Directors were not willing to allow concrete to be used to that extent. I wanted to use concrete. Piles were driven to the rock; they were sawed off and the building put on top. These next six views simply show the time it takes to construct a steel building. These views are of the Fisher Building eighteen stories high. The first view is on October 12th; the next is one week later, October 19th, and the next on October 26th. And the next is on November 10th, two weeks later.

A Member: Working night and day.

Mr. Shankland: Yes. The next view is taken on December 12, just two months from the time the first picture was taken. The next picture is in the April following and shows the completed building; it was rented from the first of May.

Mr. Denison: It hadn't time to settle.

Mr. Shankland: It was built on piles.

Mr. Wickson: Mr. President, we have all listened with great pleasure to Mr. Shankland's paper. He should live in a civilized place where they have a bottom to build on, not in a place like Chicago where they can't find bottom without going so far down. I do not wonder they have to pay so much attention to fire proofing when they have to go so near the centre of the earth to get a foundation. I want to ask a few questions. Mr. Shankland said that in calculating the load on the ground he does not pay any attention to the live load on the clay. Is that the case in all kinds of soil?

Mr. Shankland: It is the case in everything in Chicago. Of course a factory building or warehouse is always built on piles and there you take in a certain proportion of the live load. But in the spread footing of an office building the live load is not calculated.

Mr. Wickson: That applies more particularly to Chicago rather than universally?

Mr. Shankland: Yes.

Mr. Wickson: In looking over the Building By-laws of Washington I see that they take into consideration a considerable portion of the live load, thus following certain authorities.

Mr. Shankland: You naturally would if you did not want to get too great a settlement in the building.

Mr. Wickson: What do you say the proportion of concrete is in the caissons?

Mr. Shankland: One, three and six.

Mr. Wickson: How near are the caissons built to the party wall in that building you mentioned?

Mr. Shankland: They are built in the centre of the party wall; it is on a street on two sides—it is The First National Bank building. They are built in the centre of the party wall on the other side.

Mr. Wickson: In a case of that kind are the builders allowed to go to the street limit with foundations.

Mr. Shankland: They are allowed to go out to the kerb line.

Mr. Wickson: You have spoken about concrete and its uses; you have also given us some illustrations. Although concrete is being used so much in some respects I have found great difficulty in getting any data when I wanted it for concrete building—I mean the superstructure, not so much the foundation. It is rather a new thing; but still it is being used in some places. Can you give us any way by which we can get data for the strength of the superstructure of a building.

Mr. Shankland: Elsner & Anderson of Cincinnati are trying to get a permit for a sixteen story building. They have not succeeded in getting the permit yet. I do not know how they have figured the concrete. I looked over the plans and, taking the floor load at 100 pounds, and the concrete itself is seven inches thick in the floors, I found they had 83,000 pounds on the basement columns without taking into account the floor itself.

Mr. Wickson: In your address your criticism was largely as to concrete floors.

Mr. Shankland: Concrete floors altogether.

Mr. Wickson: If we take the dictum of a paper called "Fire Proof" we would not use concrete in any shape. It says "During the mediaeval period concrete was extensively used for tombs; the same is true even unto this day." I suppose we will have to wait for further development in regard to superstructure, in building.

Mr. Shankland: There are going to be great advances made in reinforced concrete in the next few years; but we do not know yet how they are going to take care of a concrete building.

Mr. Wickson: In your address and also in an article in the last "Brick Builder" there is this clause, "Good Portland cement even in thin layers is an effective preventive of rusting . . . . . it is of the utmost importance that the steel be clean when bedded in the concrete." It seems to me a great difficulty is getting the steel actually into the building without spots being exposed, even in the handling of the steel, provided it is properly treated at the mills. I suppose in very large buildings they have some way of overcoming that; but in the ordinary building such as we get in Toronto what is to prevent these places from being exposed to rust?

Mr. Shankland: We used to give it a coat of oil at the mill and a coat of paint at the job, and a second coat after erection. We do not now paint it at all till after erection. A little red rust won't hurt steel at all; it is the mill scale which if painted over will come off sometime and take the paint with it.

Mr. Wickson: Then if the steel be delivered on the job properly clean, it is quite sufficient to paint it then?

Mr. Shankland: After erection.

Mr. Wickson: With the use of the wire brush.

Mr. Shankland: That is used after erection. But after two or three months the greater part of the mill scale is off, and what remains is loose enough to be easily scraped off.

Mr. Wickson: In the steel caissons for the concrete bridge piers you showed on the screen, you said the steel work was for bracing against the wind. Would that steel ever rust?

Mr. Shankland: It has got to be painted outside and is right up against concrete inside and won't rust inside.

Mr. Wickson: It depends on the paint outside.

Mr. Shankland: We investigated a good many buildings in Chicago last spring; the oldest was about fifteen years old. We cut into the foundations of eight or ten or a dozen of them and we did not find a particle of rust in the foundation. Some places we had to bale the water out when we cut away the concrete. But the blue-black of the mill was on them in every case; there was not the faintest indication of rust. Steel should not be painted when bedded in concrete.

Mr. Wickson: That leads me to ask another question. The preservation of steel seems to be very complete where it is coated with cement, and I notice in the "Brick Builder" also that there is a statement that the use of hollow porous terra cotta blocks in connection with the cement is now considered to be an excellent method. I did not quite see how they would use them. Was it a matter of entirely coating or casing the steel work with the cement first?

Mr. Shankland: Plastering against the beam and tile.

Mr. Wickson: The columns would be filled as you mentioned.

Mr. Shankland: Yes.

Mr. Wickson: I am not sure whether it is a fair question to ask you if any of these patent paints so extensively advertised have been found to have special merits.

Mr. Shankland: An architect does not get a chance to see the steel after it is in the building. I have always followed the best bridge engineers' practice in the United States and that means red lead and linseed oil. I have never used any of the patent paints. If architects had a chance to investigate for themselves they might be able to do it; but, as it is, the only thing is to follow your leader.

Mr. Wickson: Have you ever on any occasion found the beams which are sent out from the mills not sound? What defects have occurred? Are they tested at all at the building as they are used.

Mr. Shankland: Only surface inspection. That should be made at the mill.

Mr. Wickson: Is there any other test.

Mr. Shankland: No. There couldn't be any other test. We have an analysis of the steel at the mill; and then the surface inspection is made to see that there are no surface defects.

Mr. Wickson: I ask you that because there were a couple of cases I happened to hear of in which beams collapsed or broke before they were really in place, after they had been delivered at the building.

Mr. Shankland: I do not think that has happened for a few years. When they first started manufacturing steel they got internal strains in the steel. When the market building was in progress they unloaded a beam from a wagon on the street and it split up about six feet. But now they are making so much better steel than they did that it is not dangerous.

Mr. Wickson: Could you give us approximately what the percentage is of extra cost on a building which is made all fire-proof over one that would be well constructed without being fire-proof?

Mr. Shankland: I could get nearer doing that a year ago than now. In the present conditions of work it would be hard to say. It would run from twenty-five to forty per cent. Steel itself is forty per cent. higher than it was two or three years ago.

Mr. Wickson: There is one other question I wanted to ask you although it hardly comes under your paper; I am going to ask it for the general use of architects. What are good hand books to use for construction formulae.

Mr. Shankland: The best books are the Carnegie and Pencoyd pocket books.

Mr. A. H. Gregg: What about the various text books?

Mr. Shankland: I hate to discuss books of that sort in a gathering like this.

Mr. Denison: They are compilations.

Mr. Shankland: That is it. You can't depend on all being reliable. The American Bridge Company is getting out a specification that promises to be very valuable; it will give floor loads and methods of construction, the building laws of the different cities, and a great deal of data of that kind.

Mr. Wickson: I should like to be the mover of a vote of thanks to Mr. Shankland for his paper.

Mr. Jarvis: Mr. Wickson asked a question with regard to data for figuring the strength of concrete. I do not see why that should not be a very simple thing to get at, by going to the School of Science and having tests made. It is a very simple matter provided we are always sure of the cement; and that is not a difficult proposition either, so long as you have it tested one week before the time that it is to be put into the works. I am sure that it would be one of the most accurate things in the world do deal with, just as accurate as steel, because it is so very positive; that is, cement is a positive article to deal with, and so is your crushed stone, if you have them both right. With regard to making beams and columns of concrete, it seems to me that that is also a very simple matter to deal with, having them strengthened with steel rods to increase the tensile strength of the concrete and that it would be a splendid thing for the Association to take up with the School of Science through Prof. Wright. I am satisfied myself that there is nothing in the world equal to cement concrete armoured with steel for almost every kind of building construction which will be better and cheaper than steel. I happened to pick up a paper in Prof. Wright's office a few days ago which told of some engineer reading a paper, to the Society of Engineers

in Cleveland which went as far back as the time that the Pantheon at Rome was built, which has a dome of 142 feet span built entirely of concrete. He says that this has stood the elements for nearly 2,000 years without the slightest weathering; and that in England, in certain places where the natural stone was used for facing, and concrete was used as a backing, that the natural stone has entirely disappeared and that the concrete, which was intended to play the secondary part, is there as good as the day it was put in. In this paper the engineer says that we are returning with rapid strides back to the old and time honored masonry construction, not of bricks and stone, but of artificial stone, namely concrete armored with steel. I should like to ask Mr. Shankland if an artificial stone composed of Portland cement and crushed stone in proportions of 3 to 1, the stone having the dust removed, would not be absolutely indestructible as to its weathering qualities. I have been studying concrete for the last two years and I do not know anything so fascinating or interesting as science and art in this study; and it is marvellous how few people seem to understand the first principles of making concrete. I have not seen it myself but I have been told by people who sell the raw material to the city that our engineers won't allow anything smaller for making concrete than what will go through a ¾ inch mesh; that, after he has got his stone from probably 2 inches to ¼ of an inch, the rest of it is cement and sand; they reject everything smaller than ¾ of an inch. The voids between the ¾ of an inch pieces would be considerable, and the amount of cement necessary to surround the sand which is necessary to fill up these voids would certainly weaken the concrete to a great extent, unless this crushed stone were graded from 2 or 2½ inches down to probably a 10,000th part of an inch, and only dispensing with the dust. If you were to crush the whole of your stone down to the size of an 8th of an inch in order to make a very fine concrete or cement stone for the exterior surfaces of buildings, and you do not want anything larger than an 8th of an inch, there would be a great deal of powder in that. It would be half powder. It would be a powder that would go through a 100th mesh; that is, 100x100 being 10,000, 10,000 grains would go through to a square inch; that should be rejected. But if we were to use from 2 inches down to the 10,000th part of an inch, so that there is not any powder left in it at all, and so that there is just enough space left for the cement to surround each particle from the largest down to the 100 mesh, it is something you cannot miss and is the real science of concrete working; and it seems to me it is just as easy to deal with as steel in figuring out beams and columns. But you have to get your formulae by actual test.

Mr. Burke: I have very great pleasure in seconding the vote of thanks proposed by Mr. Wickson. I would like to ask Mr. Shankland if he has made any examination of the outer columns of buildings cased with half brick or with a thin terra-cotta shell, in the manner so much in vogue a few years ago in Chicago. It seems to me that steel would be more likely to suffer damage by rust in a place like that than in the foundations.

Mr. Shankland: We examined the south-west corner column of the Pontiac building, in the 8th floor, last year. That was built in 1889. The only covering it had was 4 inches of pressed brick on both sides of the corner and fire-proofing inside. There was not a particle of rust to be found, and we opened it up for about 4 feet.

Mr. Burke: Was the brick laid in cement.

Mr. Shankland: Yes; it is just 4 inches of pressed brick.

Mr. Denison: Do you ever advocate the use of common mortar in a case of that sort.

Mr. Shankland: No, not in high walls or in a skeleton building.

Mr. Denison: Mortar would not have the same effect in protecting the iron as cement.

Mr. Shankland: No; not lime mortar.

Mr. Pearson: What form of wind bracing do you think best.

Mr. Shankland: That shown in the Fisher Building; plate girders riveted in between the columns. When the wind strikes the building all the columns in that story go together. The stiffness of that floor will bring into action all the columns in the story.

Mr. Pearson: In treating the expanded metal floor your idea was to treat the floor as a column.

Mr. Shankland: Treat the floor as a stiff plate.

Mr. Pearson: If you take the stories about 12 feet high at 40 pounds wind pressure—that would be about right.

Mr. Shankland: That is very heavy.

Mr. Pearson: Well, taking that pressure, every horizontal foot of wall abutting against the end of a bay of floor would exert a pressure of 480 pounds and the cross section of a 4-inch floor per foot being 48 inches, the pressure would be 10 pounds per square inch.

Mr. Shankland: Well!

Mr. Pearson: Can we get any data or information about that?

Mr. Shankland: I do not know of any as yet.

Mr. Pearson: Mr. Barrett, of the Expanded Metal Co., is here. We should like to get information on this matter; it is important. What is the deflection of the floor for the load? This is a factor in the matter. There are three forces in action, the dead strain, the live load and the lateral pressure, and the vertical loads work against the lateral pressure.

Mr. Shankland: A heavy wind is nothing but a blow; it does not last long nor does it cover an extended area.

Mr. Pearson: I wanted to get at some data in connection with the strength of these expanded metal floors. The manufacturers tell us that 3 inches is ample to do the work, but they give no data and no information; we must work the thing out ourselves.

Mr. Shankland: What I say is that a concrete slab should not be used in a high building where lateral stiffness is necessary.

Mr. A. H. Gregg: You mean where the wind gets at it.

Mr. Shankland: Yes. For a vertical carrying load it is another matter; but in a building 280 feet high and 70 feet wide lateral stiffness is very important.

Mr. A. H. Gregg: If you do not have a building over eight or nine stories it does not matter.

Mr. Shankland: Not if the area is corresponding, if the area is great enough.

The President: When you sink long columns into the earth, do you consider the earth at all as an assistance in preventing torsion.

Mr. Shankland: Of course if the clay is stiff enough it will give some lateral stiffness.

The President: Do you rely on it at all?

Mr. Shankland: No; neither can we give any figures for a 7 or 10 foot column 100 feet high, we have never tested one except theoretically.

The President: Under a partry wall it might not be possible to insert a column of large diameter. I suppose in that case steel rods would make a small diameter possible.

Mr. Shankland: Yes.

Mr. Baker: We have all listened with great pleasure to Mr. Shankland's instructive lecture. What strikes me particularly in Mr. Shankland's remarks about concrete is the apparent poverty of it compared with what we specily here. Mr. Shankland stated that he specified one, three and six; in Toronto I think we generally specify about one, two and four or five for building purposes.

Mr. Shankland: We think you are extravagant.

Mr. Baker: I suppose we are; that is what we want to get away from, and no doubt will when our cements are thoroughly proven. In those bridge piers what load per square foot did you put on the concrete columns.

Mr. Shankland: Twelve tons at the top. In these caissons the ordinary load is 15 tons at the top.

Mr. Baker: I am not clear myself, and I do not know whether we all are in reference to your statement that you do not provide for any live loads in preparing the foundations of the interior columns. Of course 3,000 to 3,500 lbs. per square foot on the ground we would consider extravagant building here; I think we sometimes go up to 2 or 3 tons. By the dead load do I understand you to mean simply the weight of the floors themselves?

Mr. Shankland: The weight of the building.

Mr. Baker: The dead weight and lateral thrusts and everything of that kind. You do not include any superimposed load?

Mr. Shankland: This is only office building construction.

Mr. Baker: Of course if it was only office buildings you referred to the live load is small but you also referred to pushing trucks up an incline and that made me think it was in some warehouse building.

Mr. Shankland: It is a warehouse.

Mr. Baker: I should think there would be tremendous superimposed loads in a building like that.

Mr. Shankland: The outside walls settle very much more than the interior columns. The worst settlement is the walls and you never can counteract the first settlement.

Mr. Baker: Given a floor area of 200 sq. feet and a dead load of 40 lbs.—a superimposed load of 100 lbs. in a 10 storey building would raise the load on the ground from 3500 to 8500 lbs. which in Chicago might be rather high. Mr. Shankland referred to foundations going down 80 or 100 feet in the ground. My attention was drawn to a building in New York, where they are utilizing all that space for offices; in one case they are putting in eight stories of offices under ground. There is no rdason that I can see why those could not be used.

Mr. Shankland: In New York they excavate in rock. In Chicago it would be a very difficult matter to keep the water from the lake out of the foundations.

The President: Have you examined the Stock Exchange in New York? They have excavated there some 30 or 40 feet of quicksand, and the seepage in the cellar was nothing when I saw it.

Mr. Shankland: In the Sherry Building they have put in a waterproof caisson and there they started at the surface on one side and had to go down 80 or 90 feet at the other.

Mr. Baker: What is approximately the cost of fire proofed buildings per cubic foot in Chicago.

Mr. Shankland: They run from 35 to 50 cents. That depends on the interior finish. In New York they cost 50 to 75 per cent. more than that on account of the interior finish.

Mr. Duck: I should like to ask Mr. Shankland what method he took to ascertain the proper proportion for concrete, that is of cement, sand and stone.

Mr. Shankland: That has been done several times in the physical laboratories; when we started crushing the limestone for the station they made an investigation of that, and the result of it in the tests was that you could get a stronger concrete to use it as it came from the crusher. All that has since been substantiated by the University of Illinois; and I think Perdue made some tests.

Mr. Duck: Is that in all kinds of stone? How about granite?

Mr. Shankland: Over at Perdue they used only limestone. I do not know about granite; it would not be so important there; it makes a stronger concrete.

Mr. Duck: The limestone in different localities varies very much. Some of the limestone is almost as fine as impalpable powder. In other sections we get a much better crushed stone.

Mr. Shankland: This limestone comes from Southern Indiana that we use in Chicago.

Mr. Duck: The process of pouring water into a receptacle full of crushed stone to get the amount of sand necessary to fill the interstices; then pouring water into this quantity of sand to get the amount of cement necessary to make a solid mass of the three substances usually comes out one, three and six, in taking a stone such as crushed boulders.

Mr. Jarvis: I should like to ask Mr. Shankland if cement made with a hard crushed limestone that would pass through an 8th sieve and be caught on a 100th, mixed in proportions of three to one, whether the water would have any effect on it so that the whole of the dust is eliminated, and no dust left, only clean particles of crushed limestone that go through an 8th and would be caught by a 100th.

Mr. Shankland: I do not think the water would have any effect on it.

Mr. F.W. Barrett; If I may be allowed to make a remark I should like to do so, as I am interested in reintorced concrete construction. Our business of course, is in expanded metal and concrete, or reinforcing the concrete floor with the mesh of expanded metal. I quite agree with Mr. Shankland on the inadvisability of excessive spans. In a concrete floor, our own practice is to keep down to six to eight feet as long as we are allowed to do it. Sometimes we are forced to make longer spans, but it is against our will. Long spans have to be built with great care. In the instance mentioned by Mr. Shankland, where part of a concrete floor fell in an Apartment House in Chicago, the accident occurred during construction, and was supposed to have been caused by a workman removing the centering while the concrete was green and not thoroughly set. I cannot say that I altogether agree with Mr. Shankland on the lateral strength of the floors; I think if you consider a concrete floor, where the beams are encased in the concrete, although the main slab is just over the top of the beams, each beam is encased in the concrete, so that the concrete slab will form a very very stiff construction across the building from wall to wall; much stiffer than you will find in a floor where the spaces between the steel beams are filled in with separate blocks of terra-cotta. Then of course the consolidation of terra-cotta depends a great deal on the workmanship of the masons that are laying it; for, as you know, bricklayers are apt to leave a great many voids. On the other hand the concrete is laid in a plastic condition, and the beams are incorporated with the slab very largely. The result with the terra-cotta is that in place of a solid construction across the floor you have a number of joints; that is to say, each beam makes a complete separation from the adjoining slab; and if you have any settlement or special extensions or contractions on the part of your building you are going to take away the strength that it has in compression, and such a floor is going to be weaker than a monolithic concrete floor. We have tested concrete floors with our expanded metal construction and while a slab of 3½ inches thick may seem very thin, tests have been made on a slab of 5 feet in width where the joist beams were fastened to girders 12 to 14 feet apart; and on a slab of that construction a partially distributed load of 4,000 pounds to the square foot, and a total distributed load of one hundred and sixteen thousand pounds, was put on that panel, and it did not go through. Mr. Shankland says if you set a slab of concrete up on edge it has not much lateral strength; but I think it has more lateral strength than a slab of terra-cotta of the same size set up on edge; I know that, for I have tried it. We can put up a partition two inches thick and it is a good working partition, but if you put up a terra-cotta partition of double that you can push it over with your foot.

Mr. Denison: It depends upon the foot, doesn't it?

Mr. Barrett: I know we had to rebuild a lot of terra cotta partitions because they fell down in putting other work to them. Then again as to the fire-proof quality of concrete, as compared with terra-cotta blocks, I think Mr. Shankland may perhaps know of a fire in Pittsburg a few years ago in which two buildings were damaged by fire; one fire-proofed with reinforced concrete and the other with terra-cotta blocks; one building on each

side of the original fire. The building where the reinforced concrete floors were, stood the fire which burned out all the windows, doors and contents of the building on that side, but the floors were intact after the fire, and the repairs were made so quickly that inside of a month the building was reoccupied. The damage was to the superficial parts, the woodwork and that sort of thing. On the other hand the building fireproofed with terra-cotta blocks, on the other side, caught fire and it not only injured the floors but it absolutely destroyed them; the terra-cotta floors fell down though to the basement.

Mr. Duck: Was that hard tile or porous.

Mr. Barrett: I could not tell you.

Mr. Sbankland: You remember that the engineers that reported on those two fires sent in very diverse reports.

Mr. Barrett: Yes; the engineers at that time favored the concrete, and the architects the terra-cotta blocks.

Mr. Shankland: The city I think appointed three experts; I do not say they had three reports, but they had two.

Mr. Barrett: They had two; the engineers reported for the concrete, and the architects reported against it. Then the Schiller Theater in Chicago was subjected to a fire test, and the terra-cotta cracked and split and fell off very largely. On the other hand while we cannot recall many buildings giving tests of very severe fires on concrete construction, largely because I suppose the fire protection systems are so complete that they do not have very large fires and they are able to put them out; but there are no instances where buildings have been very seriously damaged. In Montreal recently there was a building where they had concrete walls, and a great deal of the other parts of the buildings were of wood; all this wooden construction burned out and subjected the concrete walls to a very hard test. It was a very hot fire, but the concrete stood it all without any damage and it is as perfect now as the day it was built. Tests have been made with small sections of the terra-cotta work and concrete; they have been subjected to an intense heat and made red hot. Teara-cotta blocks made red hot, then taken out and subjected to cold water will crack and be very seriously damaged; a cinder concrete block of the same dimensions put into the fire and heated red hot and taken out and subjected to cold water is very little affected.

Mr. Denison: This discussion reminds me of the rival safe agents after the Chicago fire who were calling upon a man who had been burned out. One said, "Do you know that when Jones' building was burned down all his papers were in one of our vaults and, when the fire was out, they opened the safe and what do you think?" The man said, I don't know; I suppose you are going to say the papers were intact." The agent said "More than that; there was a little banty cock in that safe, and when they opened the safe that cock jumped out and crowed." The other fellow says, "That is nothing; one of our safes was in a bigger fire than that, and when they opened the safe what do you think was in it?" "I suppose you had a banty cock that crowed too," said the other one. "No, he didn't," said No. 2, "There was a banty cock all right in the safe, but he was frozen stiff."

Mr. Jarvis: I should think that the concrete used for fire protection could not stand at all if it were made with crushed limestone or broken limestone, because the limestone under any great heat would calcine and you would have nothing but lime left. If it were made with crushed quartz or granite or some material of that kind it would be all right, but certainly not limestone.

Mr. Aylsworth: As concrete is used more and more for building walls, the question in my mind is what should be the proper treatment for the outside. I do not like the color of Portland cement and it will be necessary to treat the outside plaster with something. I would like your opinion on the question.

The President: I do not know whether you consider that within your province, Mr. Shankland.

Mr. Shankland: It is out of my line.

The President: If we have heckled Mr. Shankland as much as we can, I would like to put the vote of thanks which I have been asked to put. We are very much obliged to Mr. Shankland for coming here and standing this cross-examination; I think that when our proceedings are printed we shall find that we have got some valuable information, which will be of use to us in our work in the future.

It is moved by Mr. Wickson, seconded by Mr. Burke, that this Association pass a vote of thanks to Mr. Shankland for his kindness.

The vote was carried amid applause.

Mr. Shankland bowed his acknowledgments.

The President: Before the meeting adjourns I believe Mr. Symons has an addition to make to his report as Treasurer.

Mr. Symons: Since reporting to you yesterday in regard to the finances of our Association I have received the total sum of $461.20 that was outstanding for advertising in connection with our papers. This sum, added to that previously reported, makes our balance now in the neighborhood of over a thousand dollars. (Applause.)

It being 1 o'clock p.m. the meeting adjourned for lunch.

STONE WORKING BY MACHINERY.

A correspondent of "The Quarry" agrees with the opinion expressed by that journal that the successful working or otherwise of the wire-saw depends very largely on the constituents of the stone it has to cut, as it will work fairly well in one stone and be a total failure in the next. He says: "I have found these failures arise not only with wire-saws, but with other stone-working tools. I have been concerned lately in some experiments with pneumatically-driven chisels for stone dressing, and found them work well with many stones, but with some hard stones containing much silica they have been a failure. The stones I am alluding to are at present dressed by hand for paving, setts, etc., successfully, but when a pneumatic chisel, making some 1,000 strokes per minute, was used, it was a failure, as up to date I can get no steel to stand it, although I have tried samples from five leading English manufacturers; in all cases it turned up at the edge after a few minutes' use. After some 30 years' experience in this connection, I have come to the conclusion that stone conversion is rather a "tricky" thing, and every stone must be carefully judged on its merits.

FERRO-CONCRETE CONSTRUCTION.

At a recent meeting of the Society of Engineers, Mr. Augustus de Rohan Galbraith read a paper on the Hennebique system of Ferro-concrete construction. The Hennebique principle consists in embedding in concrete straight and cranked iron or steel tension bars and stirrups, to take the shearing stresses, together with distance pieces, the system being applicable to entire buildings from foundation to roof, inclusive. The piles used in the new dock works at Southampton, England, are built up in vertical moulds, in which are placed long steel rods, which give the required strength. These are laced together with wire stirrups, and Portland cement concrete of the best quality is filled into the moulds and rammed round the steel. After a month the pile is taken out of its mould and driven in position, much in the same way as timber piles are. The ram is exceptionally heavy, generally 30 cwt. The head of the pile is protected from injury by covering it with a helmet or iron case filled with sawdust.

The annual average cost of making absolutely necessary repairs to St. Paul's Cathedral, London, is $9,000, and it is estimated that $250,000 is necessary to put it in first-class condition and to make sure it's future.

NOVEL METHOD OF DEALING WITH STRIKES.

When the painters and decorators employed on the residence of Mrs. Herman Oelrichs, New York, fell out with the contractors and struck work, the lady waited a reasonable length of time for a settlement of the trouble, and then notified all concerned that if a settlement was not forthcoming within a week they would have no work there. They failed to come to time, so she employed carpenters and scrub women who worked under her personal direction. They tore down the scaffolds, put the paints and other articles in the street and put the rooms in order. And the painters and decorators are out to the extent of their interest in the work which she planned but has now deferred.

At the St. Louis World's Fair great fluted pillars 36 feet high and 4½ feet in diameter are now being made in a mold set in place, the liquid plaster being poured in at the top. Ordinarily such pillars are made in 24 pieces and set in place, leaving many joints that have to be carefully pointed. There will be 112 such columns on the Textiles Building.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 10th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

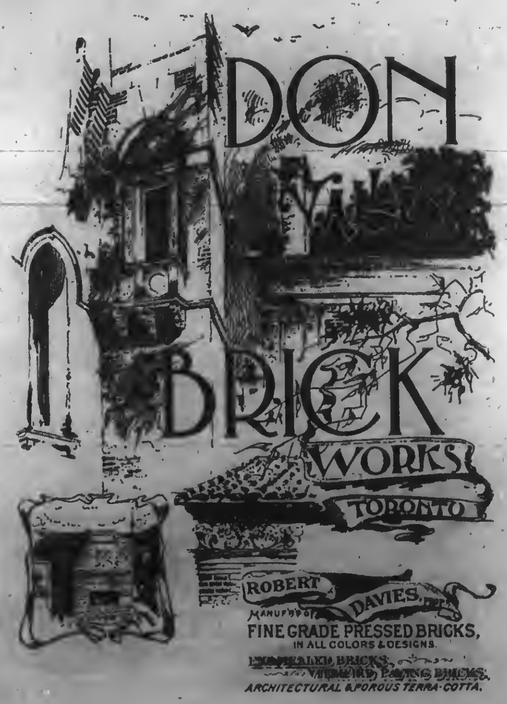
BUSINESS NOTE.

In this issue will be found the advertisement of the Robert Simpson Co., Limited, Toronto, who make a specialty of carrying out the ideas of architects with reference to interior decoration and fittings. This progressive company can be relied on for the latest designs in carpets, curtains, hangings, as well as furniture. The architects of Canada we are sure will appreciate the assistance which the company are able to give towards the fulfilling of their ideals in the line of interior furnishings. The draperies and floor covers shown by them are strictly high-grade. We bespeak for the Robert Simpson Co. the support of the architects and decorators of Canada.



BUILDERS AS LUMBER DEALERS.

The builders and contractors of Columbus, Ohio, are going to establish a retail lumber yard. They announce that they have become tired of paying the exorbitant prices demanded by lumber dealers and now propose to become bealers themselves.

The American Lumberman comments on this decision as follows: "Let them get their yard well under way and they will learn sundry things. The lesson probably will be a costly one, but there are some people who cannot learn except by experience, and experience is always an efficient. though dear teacher. As they are not lumbermen, though more or less familiar with lumber, they will have to learn about sources of supply, how to chase up delinquent cars, how to estimate the fairy tales offered by lumber salesmen, how to unravel the intricacies of freight rates and rebates, how to get rid of 10,000 feet of lumber that they had to take in order to get the 1,000 feet that they had to have, and many other problems of like nature. They will probably hire a manager and that manager will have to be paid, and they will discover that running expenses and leakage will be fully as large as the personal salary and modest profit of the lumber dealers whom they are trying to supersede."

NOTES.

A new brick manufacturing company has secured possession of a large tract of land in the north-west section of Toronto and will at once commence the erection of a plant. About 100 or more men will be employed.

The Association of Canadian Portland Cement manufacturers has just been formed, the following being the officers: Chairman, J.M. Kilbourn, Lakefield: Vice-Chairman, F.G.B. Allen, Deseronto; Secretary, R. J. Younge; Executive, Messrs. Maitland, McLaughlin, Kilbourn and Kline of Owen Sound, Stanhope of Durham, Knechtel of Hanover, Elliot of Brantford, Morgan of Longue Point, Que., and C. A. Masten of Toronto.

The Plasterers' Section of the Builders' Exchange held their first Annual Dinner December 16th, 1902. An interesting feature of the proceedings was the presentation to their President, Mr. J.M. Gander, of a bronze clock and address. The Section has made great progress in the past year, having met and amicably settled all differences with employees, and are now working with the architects on a glossary of terms defining their work for specification purposes.

WE HIT THE MARK OF PERFECTION IN SUPERIOR BATH ROOM EQUIPMENT.

It is needless to suggest that a showy bathroom fitted with sanitary plumbing is one of the most attractive features in any house.

However you may not know that we manufacture the widest and most artistic line of sanitary bathroom equipment and accessories in the Dominion.

All styles, combinations and materials are embraced in our stock which is designed with particular attention to the most perfect sanitary construction and the highest artistic appearance.

Our prices are so attractive on superior goods that no bathroom should be equipped without thorough consideration of our offerings about which we are always pleased to tell you.

Plumbers' Specialties. TORONTO, ONT.

BY THE WAY.

Among the restrictions which are being imposed by the city authorities of New York as safeguards against fire is one which prohibits after the beginning of this year the sale and use of parlor matches. Another regulation compels the use of fire-proofed wood in lofty structures, and large quantities of material called by this name have been rejected by the Building Commissioner as worthless.

× × ×

Mr. M. B. Aylsworth, a well-known Toronto architect, has recently returned from Port Arthur and Fort William, where he was engaged for four months in the erection of a hospital and other buildings. He states that building progress in these northern towns is only limited by the difficulty of securing workmen. Bricklayers are being paid $7 per day and labourers $2.50 per day. There are no vacant houses, and not enough mechanics to put up the new ones which the citizens wish to build. Each of the railways will be compelled to build at least one elevator every year for some time to come to provide necessary storage for the rapidly increasing supply of grain.

× × ×

In reply to an English draughtsman's enquiry as to the chances of employment in Canada, the Canadian Emigration Commissioner, in London, Mr. W. T. R. Preston, advised the young man that personal application would be necessary, and that the best time to come to Canada would be in the spring, when other employment could be secured if an opening should not present itself in the line of his usual employment. There never was a better time than the present for efficient architects' assistants to secure employment in Canada, and especially in Toronto. The demand far exceeds the supply, and competent young men in this line from Great Britain arriving here about March or April would be almost certain to secure immediate employment.

× × ×

The congregation of the West Presbyterian Church in New Westminster, B. C., find themselves in serious difficulty as the result of having misplaced their building. The board of managers agreed with the board of managers of St. Andrews' Presbyterian Church, that they would not build nearer than half a mile to that church. It has now transpired that the West Church stands 200 feet nearer St. Andrew's than the specified limit, and the Presbytery has been appealed to by the congregation whose territory has thus been invaded. That body after much debate has allowed the congregation of West Church five months in which to remove their building and thus fulfil their obligation. To do this will cost $1600, and as the church property is heavily mortgaged, this becomes a heavy burden. One is led to wonder what possible injury could result to the complainants from a mistake which placed a sister church 200 feet nearer to them.

"Alas for the rarity
of Christian Charity."

Sewage Disposal in Toronto.

The Toronto City Council have shown good sense by throwing out the recommendation of the Board of Control that the citizens should be asked to express by ballot their approval or disapproval of the proposal to install the septic tank system for the disposal of sewage. The City Engineer was sent to England last year to investigate sewage disposal methods. He has presented his report. If the Council have confidence in him they should act on his recommendations. If they have not full confidence in his judgment on this particular matter, let them appoint an expert to advise and act with him. What can the average citizen be expected to know about the merits or demerits of particular methods of sewage disposal for a large city? Let the Council and their officials deal with the problem and assume full responsibility for the resulting success or failure.

A Carnegie Library for Toronto.

The offer of $350,000 to Toronto with which to build a Public Library has brought on an acute attack of public debating upon the subject of Mr. Carnegie's grants. We can sympathize with the point of view of every one without seeing that it becomes the duty of the City Council to attitudinize in support of it or of any view but its own or what should be its own—whether or not it is for the interest of the citizens, as regards the question of having and maintaining a public library, to accept this grant and its conditions. Col. Denison may object to the intrusion of Americano-Scotchmen in the affairs of Canada; there is something noble and inspiring about this gentleman's stout Canadianism. Mr. E. R. Osler may consider Mr. Carnegie's offer impertinent; we are glad to have Mr. Osler take this stand, for it is certainly pertinent that the exceptionally wealthy should begin in Toronto that practice of endowing public institutions which is doing so much good in the cities of the United States; and Mr. Osler, who is liberal himself, is just the man to introduce into wealthy circles in Toronto the idea that one of the privileges of wealth is the endowment of beneficent and educational institutions. The Toronto District Labour Council may "protest against the acceptance of any alms or contribution . . . as an easement to the conscience of this man . . . who imported into the Town of Homestead a gang of sluggers, known as United States deputy marshals, whose presence resulted in the loss of life of our brother workers"—who were out on strike in July, 1892. This too is an interesting demonstration, marking the progress of thought in these matters; but it is not the function of the City Council to discuss Mr. Carnegie's wealth, only the portion of it which he offers for their use:—whether it is enough for the purpose and whether the accompanying obligation is too great to undertake as a consequence of acceptance.

The interesting questions really are whether the money—from which a large subtraction must be made

for building a branch library—is enough; and where the building should be placed. The money is certainly enough to make any addition to it a light matter and the pertinent question for the City Council seems to be whether they would rather provide the whole amount or the small part that it may be necessary to raise to supplement Mr. Carnegie's grant. It is only a library that is wanted. It is not necessary to aim at the general purpose arrangement which spoils so many libraries and adds unnecessarily to their cost—combining an art gallery, museum, etc. The project of an art gallery has already been under consideration in private circles and there is some prospect of its being built under auspices that will insure its being a good thing.

As to the question of site—it seems obvious that the central public library should be down town, where most of the population collects during the day. Between those who work daily in the city and those who come in to shop, to attend the theatre matinee, etc, the city proper is frequented, during a week, by nearly the whole population, and there is no other part which is. People live at opposite ends of the city and pass through the central part on the fly on their way to and from the business part, what we have called the city proper, or what is usually called "town." It is in town therefore that the central public library should be placed; for it is only there that the business part of the population, who work in town from early to late, would have a chance to visit it at all; and it is only there that the part of the population, whose daily occupation is domestic, could include the public library in their town round instead of being obliged to make a special visit to it at the cost of more time and an extra street car fare.

Mr. William L. Symons,
President Ontario Association of Architects, 1903.

If the building is to be down town the site does not seem difficult to choose. There is plenty of room vis-a-vis of the City Hall, and the buildings to be removed are unimportant; the situation is probably the most convenient that could be chosen, and the conjunction with the City Hall, like the conjunction of a planet with the moon, will give greater importance to each. It is a pity that the site adjacent to the City Hall on the north side of the street has been occupied by a private building. Here, in the sunlight, where its retirement from the road would have increased the space about the City Hall, was the site for another public building; but there is a sunlit corner still available on the east side of Bay street, and there the Public Library should be placed.

OFFICE MANAGEMENT.

(Concluded.)

Memo Record—The satisfaction of getting notes down in writing is apt to be delusive unless there is a certainty of the notes being forthcoming when wanted. A scribble book for all notes, dated at the beginning of every day, does very well in a small office, but as soon as the office rises above one man power and there must be more than one scribble book, it becomes evident again that the only way to provide for expansion is to keep everything together that refers to each piece of work. In the case of notes of all kinds the simplest plan is to keep a scrap book for each job into which shall be pasted every note that is made in connection with it. A standard size of note pad, distributed through the office and ready to every one's hand, will produce neater and more orderly results. Should a client come in with instructions the first thing is to date a sheet of the scribble pad. When he is gone the notes should be pasted in at once, both for security and also to keep everything in order of date.

Call Book. — The office boy should keep a book on his desk in which to enter under date the name of every one who calls on business of the office and whom he saw. The time of coming and going should be entered. In the case of a client it may be useful to exhibit in support of an account a statement of the number of hours of office time consumed in interviews.

Extras. — Here is a great centre of trouble in building, not always on account of the amount of the extras so much as because they are unexpected or incurred without permission. It seems to be commonly held among architects that extras should be kept in the background as long as possible. If this is intended to further the maintenance of smooth relations with the client as long as possible, it is a mistake, ministering only to a deceitful smoothness which must react upon the architect's mind and effectually destroy the frankness that ought to be the essential condition of his dealings with his client. If a statement of extras is delayed in the hope of reducing them in some way before the day of settlement, the path is made easy for temptation to juggle with the extras and the contract to drop some item of the contract in payment of extras, or to substitute a cheaper material for a dearer, and set off the amount of the difference against the extra account before making the statement of extras. Either of these methods of reducing the extra bill may be a judicious decision, and cheerfully accepted by the owner; but to make them without his knowledge is an act which bears a strong symptomatic resemblance to dishonesty; for the contract which the owner has accepted states the work which he has a right to expect unless he agrees to deduction from it.

The wisest plan is to keep the statement of extras as far as possible abreast of the progress certificates. For this purpose as well as to avoid disputes it is well to settle the amount of the extra, as far as possible, when it is ordered, and to give all orders for extras in writing stating the estimated cost. For this purpose a form is necessary, printed with headings for the building number, order number, date, contract, description of work to be done (with plenty of space left for this) the cost, and signatures of contractor, owner and architect. The form should be issued in triplicate, and it would be best to have it in book form with one stub for each three blanks. If there is to be but one writing with carbon paper between the blanks, this would require a page with three divisions perforated between and printed alternately on the front and back of the page, so that the printed surface of all three may face upwards when they are folded for reduplicate writing. The three blanks should have "owners' copy," "contractor's copy," "architect's copy" printed across the face.

Contracts.—The contract should be made out in triplicate; a copy each for owner, contractor and architect, and the office copy should have attached to it the tender and memoranda to show how the contract sum was made up.

A set of blue prints, as less susceptible of alteration, is usually set aside for the signed contract drawings. Subsequent alterations may be then made on the tracings and should always be dated. A print of each alteration may be made.

Certificates and their Record.—The certificate form should have headings on the stub for a full statement of the progress of the account and these should be repeated on the certificate. The items should run: Contract amount, extras, total, deductions, net total, (thus taking account of extras and deductions to date of issue of certificate) former certificates, this certificate, drawback, total, and balance on hand (when total of certificates and drawback is subtracted from the net total above.) The drawback and balance do not seem to be inserted in the American certificate. The building number and progress and trade numbers of certificate should be given and the date; the name and address of the owner or his agent to whom the certificate is addressed and the contractor's name. All information on the face of the certificate should be entered on the stub. It seems to be usual in American offices, to have only a brief note of number, date, amount and contractor on the stub, but to keep a letter press copy of the certificate, and the form is sometimes printed in aniline ink for the purpose.

Frank Miles Day & Bros. print on their certificates the following excellent notice:—

"On making this payment the owner should assure himself that his interests are protected by insurance sufficient to cover his liability in the increased amount resulting from this payment."

This notice is supplemented by a note to the same effect, on a form added to the certificate with a perforated attachment. It reads thus (after number, date and address):—

"We have this day issued to.....a certificate of payment on account of.....contract for work on your.....We call your attention to the insurance clause of your contract and to the notice as to insurance on the certificate.

Yours Truly

.....

For the record of certificates and contract accounts, the writer in the The Brickbuilder recommends a folder for each contract. Copies of contracts, orders and accepted estimates are kept together in the respective folders. These documents are apparently fastened on the inside. The record of accounts are made on the outside and are displayed at one opening, thus:—The sheet, which is in the proportion of 3 long to 4 wide, is folded vertically in three; the middle division which is to be exposed, is titled with the building number, the contract, contractor's address, etc., the side divisions have recorded on one the certificates issued, with columns for date, amount and total to date, on the other a statement of deductions and extras in four columns under four headings, viz., date, order number, deduction, extra. The deductions and extras in parallel columns show at once the progress of the extra account. The bunch of folders having to do with one building are kept together in a special file. As an assistance to picking out the right folder with ease, the tail of the outside fold may have printed on it a list of all trades, and the trade accounted for by each particular folder may be underlined.

It is worth notice also, in pursuance of the idea that printed headings for everything that should be filled in are a necessary guide to prompt the memory of office subordinates as to method and ensure orderly work, that across the head of the exposed surface of the contract folder is printed "file herein contracts, accepted bids and orders."

Superintendence Reports:—In a large office where superintendence is done by an outside man or a draughtsman, a form of superintendent's report is essential, but even when a principal oversees the work, it is desirable to keep a record of progress, and to keep a reminder of work not done according to contract that it may not be lost sight of until corrected. The form in use by A. J. Manning serves both as an instruction to an unskilled superintendent and as a reminder to an experienced man. It has the following heads with space sufficient after each for the sort of note that follows:—

"Weather conditions....How much time lost owing to bad weather....Number of men at work....What doing....Work done since last report....Work not according to contract....Defective work formerly reported made good and how....Materials delivered since last report....Materials wanted on the work now....Materials not on the ground that will be required two weeks hence....Mechanics wanted on the work....Mechanics that will be needed two weeks from this inspection....If work is delayed or will be delayed for want of materials, details or other reason, state for what, and include any remarks not covered by above inquiries"....

If this form or one to the same purpose is filled in periodically the work is not only more methodically looked after but there is a continuous record on file of the progress of the work.

Work Slip.—A convenient device to keep work moving with little personal oversight is the workslip. The following heads for entry are taken from a slip in use in the office of George B. Post. After the building heading and slip number are as follows:

"Title of work....Origin and date....Drawings ready....Drawings submitted....Drawings approved....Specification ready....Contractors affected....Estimate invited....Estimate ready....Estimate Submitted....Work authorized....Contract awarded or orders issued"....

When the last item is dated the slip may be filed away. The "origin" may be the Memo Record, the authorization a letter. A rubber stamp for such constant authorities will be found useful; in particular a rubber stamp, lettered "vide letter....19....," will be found of great service for marking, authorization or directions on drawings, records, reports, work slips, etc.

"C. A. & B." STUDENTS' COMPETITION.

The committee of award in the CANADIAN ARCHITECT AND BUILDER'S Students' Competition for a $2,500 town or suburban house, have awarded first place to the design by "Canada," second place to the design by "Pen," third place to the design by "Mayfield," and honorable mention to the design by "T Square, Jr." The judges submit as a part of their report the following criticisms of the several drawings :

"CANADA" (design placed first)—The front would be much improved by designing the main gable more in scale with the rest of the work. The designer has not sufficiently studied the effect of the lines of the semi-circular gable above the rafter lines of the roof. The effect in execution would be even more clumsy than on the drawing.

In regard to the plan, pantry accommodation should have been provided and connection from the kitchen to the dining room without having to go through the main hall. The bathroom is too small. The sub-dividing of the basement should have been shown.

"PEN" (design placed second) has won his position in this competition not so much by what he actually presents as by the possibilities of his design.

In the first place the drafting is very incomplete, particularly in the planning ; while the lettering is unnecessarily large and very ragged.

He certainly should have indicated more clearly than he does the steps approaching the entrances ; also the wall section on the front elevation is entirely out of place, hindering the completion of the side elevation of the dining room extension, which is far more important than the wall section.

In the plan there seems no reason why the staircase hall should be shut off from the entry hall in the manner it is; nor why the bed room over the dining room should be practically entered through a closet.

The stairs would have extremely high risers indeed to reach the first floor in the space allotted to them, but however there is no doubt space enough in the hall to permit of them being made adequate.

The principal charm of "Pen's" design is the quiet and thoroughly domesticated character of the elevations, which are rather weakly rendered, but are entirely free from over-strained or exotic features, and had it been more carefully worked out in plan and also more carefully rendered in elevation, it would have been more worthy of the design, which is quite charming and capable of being put into very effective shape.

MAYFIELD (placed third).—This design shows a large amount of restraint; is simple in plan and the draughtsmanship is good. As regards the plan, the direct entrance to both the dining room and hall from the kitchen would be undesirable. This could have been obviated by moving the kitchen more to the north, and by placing a pantry and small hallway on the south side of kitchen, the pantry to project over dining room with serving door on west side of dining room. The servants' room would then be reduced in size but with closet in north west corner it would be ample. It might be said that most clients would object to a servants' bedroom opening off the kitchen. In the ground floor a door should connect the dining room and front hall. The exterior design while plain, is original in conception. The barge board seems a little heavy and the method of projecting the ridge board is hardly commendable.

"T SQUARE JR." (Honorable mention)—This design calls for great commendation, but is open to the insurmountable objection that the cost would far exceed the amount allotted, and so was ruled out of consideration as a prize winner.

The ground floor plan is excellent, and the Pergola introduced is at once unusual and suitable.

In the first floor the objection to be noted is that inferior rooms such as w.c., linen closet and cupboards, in addition to the bathroom, take up the south front of the house, while a bed room is placed facing north.

The elevations are extremely well handled, both as to design and rendering. The general composition is good, materials properly used, and the character is both reserved and interesting.

The details submitted show careful study and skill in obtaining a good result by simple means.

"UTILITY."—This design shows careful study and aptitude in planning, design and rendering, but, as in the case with "T Square Jr.," the cost would far exceed the stipulated amount.

One feels in regard to the ground floor that more advantage might have been taken of the south aspect.

In the first floor plan the exposure has been more considered, and altogether the arrangement is good.

The elevations are well rendered and the design on the whole is satisfactory, although better results would have been obtained if more distinct character had been aimed at.

"BOBS."—This design could not be built for the amount stipulated in the conditions.

For the size of the rooms the hall area is too great and there is much waste of space on the first floor wing, the bath-room being unnecessarily large and the bedroom cupboard out of proportion to the size of the room, and the linen closet inconveniently arranged off the bathroom.

The main outlines of the elevations are good. Much of the effect thus gained has been lost in striving after effect by detail, as for instance, in the chimneys.

The verandah is especially weak in design.

The interior details are good. The design for the front entrance door is bad.

"MULTUM IN PARVO."—The plan and elevations on the whole are good but commonplace. There has been too much striving for effect in the main hall, ground floor. If more room could not have been obtained it would have been better to omit the fireplace and to have formed a vestibule, doing away with useless small closets, and possibly the beams and column. The plans and perspective are neatly executed.

"CYMA"—The author of this design has evidently made a conscientious effort to plan an everyday house to suit the average householder—but a greater effort might have been made to improve upon the ordinary run. The position of the pantry between the kitchen and front hall is objectionable and it would have been better to have used this space for a back hall and rear staircase, placing the pantry and a cupboard on the south side of kitchen. Upstairs, such an arrangement would allow the bathroom to be put on the north-west corner, with better light. The stairs to attic as shown, over rear stairs, give little headroom, a matter of vital importance in planning. The alcoves off the parlour and main bed-room might be made pleasing features, but the proportions of these rooms are not of the best. The single sliding door between parlour and dining room is too large for practical purposes. As regards the exterior, the gable over the square bay requires support at north-east corner for appearance sake and the pediments of verandah roof are unsatisfactory without breaks in cornice line to give them a meaning, For the front door and side light a more symmetrical arrangement would have been desirable.

"IF"—This design shows a plan of a character well suited for a suburban or town house, but a vestibule is an essential in a climate like ours, for which it is assumed the house is intended, and this could easily be arranged. In the dining room the fireplace might have been omitted and the space provided for a side-board. The first floor plan is good but would have been improved, if at least two of the bedrooms opened off the front hall. The perspective drawing is certainly distorted and hardly gives the correct impression. The large gable in front and short ridge from front to back would look out of proportion if correctly drawn and it would have been better to have omitted the more easterly of the two gables on the north side. The finish of octagonal bay, etc., under the overhanging part of first floor as shown looks crude. On the whole with a little more study of the elevations a much more satisfactory design might have been evolved. The two mantels shown are rather weak as to design, and the drawing does not give a proper indication of the material or construction. The draughtsmanship generally is commendable and the lettering is neat excepting in the floor plans.

"MAPLE."—The plan of this house is one of the best, being compact with space well utilized and careful attention given to the disposition of rooms, aspect, etc. The dining room with eastern exposure is well placed and the finishing of the first floor hall in bay to the west is satisfactory, thus allowing space for two good bedrooms to the front. The cutting of the corner of the south east bedroom might have been avoided, as it is almost always an undesirable feature in a room. The exterior massing is good, but the detail is somewhat mechanical. The two small circular bays to the south are rather trivial and the half timbered spandril over verandah, finishing against the brick wall is a feature which would be unsatisfactory in execution.

Egg, 24 Tupper Street, Montreal ; "T Square Jr." (honorable mention) Clarence Thetford, with Messrs Darling & Pearson, Imperial Bank Building, Toronto.—EDITOR C. A. & B.]

MATERIALS, METHODS AND TERMS USED IN PLASTERING.

At the request of the Toronto Chapter of the Ontario Association of Architects, Mr. W. J. Hynes, on behalf of the Plasterers' Section of the Toronto Builders' Exchange, has prepared and submitted the following description of materials, methods, tools and trade definitions used in plastering, the object being to assist in bringing into use specifications that shall be more nearly uniform than those heretofore employed :

DESCRIPTION OF MATERIALS USED IN PLASTERING.

1. No. 1 WOOD LATH consists of white pine, cedar or spruce, free from large knots or bark, 3/8" thick, 4 feet long, in widths of 1", 1¼" and 1⅜", of uniform dimensions.

2. No. 2 WOOD LATH consists of hemlock, hard pine and culls from white pine, cedar or spruce, of irregular dimensions.

3. EXPANDED METAL LATH made from sheet steel, cut and expanded, may be procured either in the naked steel or painted. The Expanded Metal Company, of Toronto, manufacturers.

4. HAYES' METAL LATHING is made from sheet steel which is perforated, with the points of perforations turned back to form keys. Manufactured by the Metallic Roofing Co., Toronto, either plain or painted.

For either metal lathing the bearings require to be not more than 12" centres.

5. GREY LIME from Georgetown, Limehouse and Milton is generally used for mortar for the under coats in plastering. It should be well burned and used while fresh.

6. WHITE LIME from Guelph, Galt, Innerkip and other places is used for the finishing coat. Like the grey lime it requires to be well burned and should be made into lime putty while fresh.

7. WHITE ROCK FINISH, a new preparation on the market appeals strongly for consideration, from the fact of its being scientifically ground, and slacked with only sufficient water to complete the slacking, leaving the product in the form of dry powder which can be conveniently handled and used same as lime putty. Manufactured by the Imperial Plaster Co., Toronto. To be used according to the directions of manufacturers.

8. PLASTER—Made from Gypsum requires to be finely ground and properly calcined. Should be white in color, and of uniform setting properties. Our market is chiefly supplied by the Albert Manufacturing Co., of Hillsborough, N. B.

9. SAND for lime mortar should be sharp and clean but not too coarse ; for cement work, coarse sand is best.

10. HAIR should be long winter cattle or goat hair properly saved.

11. FIBRES have been offered as substitutes for hair, but nothing at present offered answers the purpose.

12. NAILS for wood lathing 1⅜" long, of good weight and head. For expanded metal large-headed slater's nails. For Hayes' lathing heavy lath of good head.

13. METAL ANGLES. Hoidge metal angles patented and manufactured here are a good protection for external angles.

14. HAIR MORTAR consists of grey lime properly slacked and mixed with clean sharp sand, to which is added sufficient hair to hold the material from falling or wasting through keys of lathwork.

15. STRAIGHTENING MORTAR made same as above with a greater quantity of sand and one third the quantity of hair.

16. COARSE STUCCO made from grey lime, or white, as desired, with clean coarse sand.

17. FINE STUCCO made from lime putty or white rock finish, mixed generally one of lime to three of clean sharp sand.

18. LIME PUTTY made from white lime slacked with a surplus of water, run through a fine sieve, and allowed to stand in vats until fit for use.

19. GAUGING is the term used to describe the admixture of calcined plaster with mortar or lime putty. The larger the proportion of plaster used the stronger the work will be. The same term is used to describe the mixing of cements with mortar, sand, lime or other material.

20. PORTLAND CEMENT gauged with lime mortar is used generally for outside work and first coat on lath work, the proportion varying according to requirements.

21. PORTLAND CEMENT STUCCO generally used for outside work and places subject to damp or moisture. when applied on lath, use one of Portland, three of sand, and add one of hair mortar. Second coat, three of sand, one of Portland, and finishing coat generally two of Portland to five of sharp sand. When used on lathing, metal lath is to be preferred.

22. PORTLAND CEMENT WORK is generally conceded to be the best base coating for Keene's or white cements.

23. KEENE'S, PARIAN, MARTIN'S generally described as "white cements," were originally patented. The base of all is gypsum mixed with alum or borax and recalcined and ground. English Keene's cement is generally made in three grades—coarse, fine and superfine—the first of a pink shade and the latter pure white.

24. FOR BASE COATS Portland cement work is generally used, but many manufacturers advocate the use of coarse Keene's and sand. This method requires that the heads of all lath nails and exposed metal work be well shellacked to avoid rust. For first coat use two coarse Keene's, three sand. For second coat use one of coarse Keene's, one sand. Finish with neat cement.

25. VICTORIA KEENE'S CEMENT manufactured in England by Cafferata & Co. allows the use of lime in small proportions. This greatly reduces the cost, not so much in the material as in the ease and speed with which work may be executed.

26. BEST'S AMERICAN KEENE'S also uses this method for plastering.

In specifying these materials it is advisable to say they shall be used as directed by the manufacturers.

27. PATENT OR HARD PLASTERS are numerous. The base of nearly all is calcined plaster mixed with sand, cement, hair or fibre, and treated with a chemical retarder which delays setting and allows time for use. They are generally good, being machine made of ac-

curate proportions and furnished at building ready for use with the addition of water only. To save cost of transportation, some are delivered ready to use by mixing with sand and water. Owing to the increased cost of this material, thinner grounds are used.

28. WOOD FIBRE PLASTER made in Toronto by the Imperial Plaster Co. is the best and most general in use here. It is supplied ready for use by adding water only.

29. PARISTONE made by the Alabastine Co., Paris, Ont., is supplied without sand and contains no hair or fibre.

30. ROCK WALL PLASTER made by the Albert Manufacturing Co., Hillsborough, N.B., is supplied without sand.

It is advisable to specify these materials to be used as directed by the manufacturers.

31. PATENT OR HARD PLASTERS make only the base or rough coats. Good stucco or float finish work may be done with them but all depend upon lime putty or white rock finish for a trowelled coat.

33. BLACKBOARDS. — Potter's Blackboard Material made by the Soapstone Finish Co., Chester Depot, Vt., is generally used. Some contractors have their own compounds and methods. They should be black, hard, smooth, but free from shine or polish.

DESCRIPTION OF WORK DONE IN PLASTERING.

1. RENDERING is a good coat of hair mortar on brick or stone walls before lathing.

2. BACK PLASTERING is lathing and plastering with one good coat of hair mortar on any framework which may be required before regular lathing is done. Back plastering, when done between timbers, is a slow and expensive process. It is better to lath and plaster the timbers and re-strap lath and plaster, as this method gives complete separation of woodwork.

3. DEAFENING is a body of plastic material laid on boards fixed between joists of a floor, composed of lime screenings and cinder or ashes, or lime and mill shavings, about 2″ thick. The use of cement in deafening is a detriment, as when made hard the deafening properties are destroyed.

4. WOOD LATHING should have joints broken every twelfth lath nailed 3-8″ apart for ceiling work and ¼″ apart for wall work. Ends butted, no vertical lath allowed.

5. METAL LATH should have bearing, not exceeding 12″ centres nailed on with flat headed nails for either metallic lath or expanded metal and if finishing coat is required must be specified "three coat work" as all metal lath must receive a scratch coat foundation for straightening. Arches, grains, or furring for heavy mouldings are best executed with metal lath.

6. ONE COAT WORK is one good coat of hair mortar or other plaster about ¼″ thick and floated to to an even surface.

7. TWO COAT WORK is one good coat of hair mortar straightened with a tool called a "darby" and floated. After this coat is dry apply putty coat of white lime and plaster with sand, if desired. The work cannot be made more than reasonably straight.

8. THREE COAT WORK is one good coat of hair mortar well scratched. Second coat of straightening mortar laid plumb and true. After this coat is dry apply coat of white lime and plaster with a mixture of sand, if desired and extra well trowelled or polished.

9. ROUGHCASTING is a good coat of hair mortar left from the "darby," and when dry slapdashed with a mixture of lime and clean fine gravel.

10. STUCCO—this term is used to describe plastering work finished with a wooden tool or float leaving a rough granular finish.

11. Rough or two coat stucco work consists of one coat of hair mortar well scratched and finished with coarse stucco applied when under coat is dry, straightened with a "darby" and brought to a rough uniform surface. This work cannot be expected to be more than reasonably straight.

12. Three coat stucco or float finish consists of one coat of hair mortar well scratched with a second coat of straightening mortar laid plumb and true and finished with a coat of fine stucco properly floated to uniform grrnular surface.

13. BASTARD STUCCO consists of work executed as described for three coat work with the exception of the last coat being composed of two parts lime putty to three of sand laid true and floated to an even surface; this is then trowelled to a hard surface but the face is not made perfectly smooth.

14. TROWELLED STUCCO is same in material and method as bastard stucco, the difference being that it is trowelled until face is brought to a true smooth surface. In both bastard and trowelled stucco the under coats must be thoroughly dry; there being no plaster or cement used in this work the success depends upon proper and uniform suction.

15. DUBBING OUT is the term given for the necessary work in preparing the uneven surface of rough brickwork or fireproofing to allow of plastering. If done with mortar it will require that not more than ½″ be put on at one time and may take several coatings to bring work to the proper surface. By using gauged mortar or hard plaster the necessary thickness may be applied at one operation.

16. PORTTAND CEMENT WORK requires same methods for stucco work as here described for mortar, the proportion of materials being as described in Materials, clauses 20 and 21.

17. TROWELLED PORTLAND CEMENT requires under coats, as described above, and is finished with two of Portland, one of fine, sharp sand, to which is added one twelfth of fine lime putty, laid even and trowelled to a fine polished surface.

18. KEENE'S CEMENT WORK may be finished as described for plastering work, the proportions being as described in Materials, clauses 23, 24, 25 and 26.

19. PLASTER MOULDINGS are formed with gauged mortar and finished with gauged putty. When weight of mouldings is not too great the mortar may be dispensed with. Owing to the danger from settlements and shrinkages the thickness of these mouldings should not exceed 1½″ in any place. All heavier work requires to be bracketed.

20. KEENE'S CEMENT MOULDINGS are executed in neat Keene's cement, either coarse or superfine as may be desired, with a backing of coarse Keene's and sharp sand.

21. PLASTER CASTINGS are composed of plaster and cast from moulds required by the design or article to be duplicated.

22. STAFF CASTINGS are composed principally of plaster to which fibre or canvas has been added before the plaster has set. Their cost is no greater than for the plaster castings and they are much stronger allowing of very large work to be made in one piece. These casts may be sawn and fixed by nailing.

STAFF calls for special attention. There is no limit to its possibilities as a decorative material either in conjunction with run mouldings for enriched members or for the production of mouldings with enriched members and decorative features complete. By its use the entire decoration may be prepared while the building is in course of erection, ready to fix as soon as work is ready to receive it, in this way saving much valuable time. The manufacturers carry full stock of such ornaments as are in general demand but work to detail requires special models, for which due time should be allowed. Specifications should state whether work is to be from stock or specially modelled to detail.

23. WOOD FIBRE PLASTER or other hard plaster may be specified for any work where mortar is used for interior, as described in previous clauses. A great saving in time can be effected by its use, particularly in winter or damp weather.

24. TOOLS AND TERMS.—Scratching is the term used to describe the cross scoring of the first coat of mortar to form key for straightening coat or coarse stucco finish.

THE DARBY is a wooden tool about three feet long, 4″ wide and ½″ thick, with two handles by means of which the first coat is two coat work, and stucco coat in two coat stucco is levelled or roughly straightened.

THE FLOAT is a wooden tool about 14″ long, 4″ wide and ⅜″ thick, used after the "darby" and straightening rod to level out the work, also for finishing stucco work.

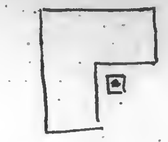
25. GROUNDS for plastering work should be of soft pine firmly nailed and made true and straight. The thickness of grounds determines the widths of frames and jambs and should be considered together. For brickwork or terra cotta the thickness here given is supposed to be fixed close to wall; if unduly packed out to straighten defective walls a dubbing out coat is necessary.

Two coat work in lime mortar on lath ¾″ grounds.
" " " " " brick 3/8″ "
Three coat work in lime mortar on lath 7/8″ "
" " " " " brick ⅝″ "
Grounds for metal lathing ¾″.
Two coat work hard plaster on lath ⅝″ grounds.
" " " brick ⅜″ "

DESIGN.*

By WILLIAM L. PRICE, Philadelphia.

Mr. President, brother architects, and friends of architecture. I have not any paper to offer you, just a few remarks that I am afraid will be rather rambling because I want to touch on a great many subjects; I want first to speak on the question of making the talk a practical talk. We have heard a great deal of discussion to-day at dinner and at other times about being practical but every time we try to be practical we turn to the ideal, because when we come to analyze what is ordinarily called the practical it is the transitory; it is the bread and butter that we eat, not for its own sake, but to make the man; the practical part of our work is only the mother of the ideal. Architecture could not exist, architects would be an absurdity if it were not that the ideal is after all the main object of mankind's search and endeavor. Now it so happens that architects are not only clothiers of mankind, but teachers of mankind, teachers for good or ill; teachers whether they want to be or no. Now I do not know of any royal road to the ideal, if I did I would not tell anybody about it, because the only thing that any man can get to help him towards the ideal comes from within and not from without. We spin our own cocoons (especially as architects) and it lies with us whether our cocoon shall be a monument or merely a sepulchre. And we must not compare those cocoons one with the other and say of this man that his cocoon is not as fine a monument as the other man's. Compare it with the man himself and ask, Did he build as well as he knew, or didn't he? That is the only question. If he built as well as he knew he couldn't help building to himself a monument and for the crowd a betterment. The architect's profession or art or whatever you choose to call it, is perhaps the most involved that there is. We have just been discussing a question of color decoration; the architect that does not consider the question of color in his buildings when he is designing his mouldings and ornaments is not designing at all. It is just as much an essential part of the design, the color of the walls or an approximate idea of the color of the walls as the moulding; they are there for the same reason, to give color effects, light and shade. One of our architects some years ago denounced American architecture as "an attempt to make something look like something else that would not be desirable if genuine." That is a pretty savage arraignment, and it is perhaps not quite so true as it was; but still it is in a large measure the truth. When we build the big structures that we call buildings, office buildings or similar buildings (they are not buildings at all in the real sense, but are structures or erections), we clothe them carefully with building material, nine times out of ten, stick it on, bolt it on. There is a building in Philadelphia in which the granite corner piers, a perfect absurdity in itself, are apparently of solid blocks, carefully and painfully cut out in the form of an "L," allowing the column to stand within it in this fashion.



1

If that is not an attempt to make something look like something else that would not be desirable if it was genuine, I do not know what it is. It is a lie that works both ways; it hurts the community and it hurts the man who did it, and hurts him worst.

Much of what I am going to say may appear reactionary, but I want you to notice one thing, that the man lost in the wilderness (and we are just a little lost in the wilderness in art matters), if he has not some guiding point, will go around in a circle—at least I am so told. So while the line of progress may be something like that—an upward slope—we may be travelling

2

a line something like that, believing all the while that we are on an upward course.

And we must not measure the line by what we can see of it; we do not see enough to make one part of it look different from another part at any time. We have to consider a great many outside things; to look at history and experience, to the architect especially that is essential. There is only one thing worse, in my judgment, than ignoring precedent, and that is following it. (Applause and laughter.)

Now I want to take you with me in a little practical talk—we are up against a serious proposition. Having secured our client, the first question for us, what next? Shall we build around that client our shell or his fitting shell? Now when we stop to think of it, how often are we trying to build the best possible monument to ourselves and not the best possible house or building for that man?

During a first interview with a client a year or more ago, after talking to him about an hour, he said, I would like to see the house you would design for me, Mr. Price, and I said I would too. Being agreed on that he then said: "Now I have told you the things that I want, the size of the rooms and the number of them; you know

* Paper read at the annual convention of the Ontario Association of Architects held in Toronto January 13th and 14th, 1903.

the site, make me a sketch of the house you think will fit these requirements." I said, "Mr. ——, I will gladly do that; I can do that, I think, but if you take that design and build it you will be a fool." And then I went on to say, "for I do not know you well enough to draw a house for you." I hadn't the slightest expectation that I would get that job, but right there I got it, because that man began to see something different in architecture from what he had ever seen before; he began to realize that this was to be his house, not an architect's house merely. Afterwards, sure enough, to show you how the good work took effect, one of the leading finishers of the city went to him and said, "Mr. ——, you are a busy man, you donjt want to bother with the designs for the inside of your house; I will refer you to So and So—we did the work for him—$47,000 worth of interior work and we did not take up two hours of his time."

This gentleman said, "Well, that settles it, you could not decorate my house or do my interior woodwork because I can see that that is your interior woodwork and not his, it does not fit him." I simply tell you that to point out that what we have to do if we are going to have real architecture is to make our product more than beautiful, more than fitting to the situation, primarily fitting the man that is to live in it or the purpose for which it is to be used. That means a pretty savage thing sometimes; it means that if we are going to build a house for a vulgar man, that we must build a vulgar house. It wouldn't be architecture if we did not. It must be better than that man; it must be what that man might be, it must represent that, but unless it has in it some element of that thing which makes him the vulgar man, in my judgment, it is not architecture at all, we are up against difficulties and limitations of that kind, and it does not seem to me to be such a bad thing after all. Fortunately the vulgar man usually goes to a vulgar architect, so that we need not often be seriously troubled that way. (Laughter.) But the fact remains that it must fit the man in some way or other, and I think the most of us (even if we do not analyze these questions of design) naturally tend to draw a vulgar house for a vulgar man. But we must be mighty careful of what we mean when we call a man vulgar. A difference in taste does not constitute vulgarity or the reverse. People have come to me and said, "I like that house out on 40th street, in West Philadelphia, and that is the limit. I have been around your town a little, but there is nothing that I have seen here that approached 40th street: it is absolutely the limit." Most of the arches on the porches are wrong side up, thus:

3

Nearly all of them. My client will say, "I like this or that house at 49th street." And instead of falling dead I go out and try to find what it is he likes about that house; very often it is a bay window on the side of it, or it faces this way or that way, or it has some other feature absolutely irrespective of design or drawing that fits the man. If, for instance, you take a man that likes brilliant colors and set him down as being ignorant and vulgar, because you have put two things before him; one good, in low tones that you care for, and one bad in high colors that you loath and that attracts him because he loves color, you make a great mistake, for that is not a fair test; you ought to put before him things good and bad in both bright and quiet colors, and you will find ninety-nine times out of a hundred he will choose the good thing Find out what it is he likes about the bad thing, give him a chance and he will choose the good thing rather than the bad. If that were not true there would be no civilization; we would have devoluted back into oysters by this time because we have done so many foolish things and so neglected the laws of nature that it must be some principle in us that seeks the right rather than the wrong, to keep us going at all. As Prof. Shortt said to us yesterday, we have gotten away entirely from the mainsprings of the art and architecture of the past, we have come to a time when neither the civic or the religious is the ideal around which we build our civilization, but the individual, the domestic. Take all these high buildings with which you gentlemen are wrestling in pain and trouble (and it is a serious trouble); what are they for? After all are they not merely the places that we go to (to get away from as soon as we can), that we may have enjoyable surroundings in our home life? That is the sole object, and while we should make them as little obnoxious as possible and keep them as quiet as possible, because they tend to ramp and rave —while we should do that it seems to me that our greatest effort should be put upon the making of the object of all this beautiful, and that is, after all, our homes. (Applause). Therefore, I am talking mainly about house design. I want to say, though, that your president yesterday pointed out what seems to me the only logical materials in which to design the office building, and that is a skeleton of steel clothed with a plastic material of some kind. I cannot conceive, though I admit I have done it myself, that it is proper to clothe a steel frame by putting brick or stone around it or any real building material: it is a lie on the face of it, for it would not stick there and stand unsupported. If we must have that kind of building let us encase it with some plastic material like cement. The engineers are looking after the bones and we are after all only the planners and decorators of it.

The most serious question, as I see it, in designing a house that we have to meet with is, what shall the concrete thing be made of and how shall it be made? Or, perhaps, how shall it be made and what shall it be made of? We will treat, what shall it be made of, first. The material must be moderately cheap. We do not often have palaces to build; we are not working for Gould or J. Pierpont Morgan, but for each other, the average community which we find around us; therefore, the buildings which we build must be cheap. They must not or should not require any great amount of ornament; and I want to point out that the bulk of the ornament that we use is used purely to get surface, and not for the value of the ornament itself. The pressed brick of good old Philadelphia was so horrible that after we once waked up and got past the marble steps and marble lintels we flew to the other extreme and brought in the tortured mud (the terra cotta man), with his substitutes for surface; and we put wriggles

all over it to make up this surface; that is what it amounts to, most of the ornament is just that—wriggles; and we smear that over it for no other reason than that we want surface; I do not think that the lack of ornament enters our mind one time in twenty when we put that kind of stuff on; I do not refer especially to terra cotta, but to all senseless ornament. It is because we are afraid the surface will look flat without the ornament, and that is a mighty poor excuse for putting it on. As I say, texture should be the first consideration, because the bulk of our building will depend for its beauty on texture and on the disposal of it's masses and not on ornament. In the first place real ornament that really beautifies the building is too expensive to spread all over it; and, in the second place, you cannot see it if you do so; it becomes merely surface, and here is where fortune favors us, as it so happens that the cheaper and rougher materials naturally have the better textures. I remember when building a house some years ago I arrived on the scaffold just as the bricklayer was starting to build a high kitchen chimney—it was my own house, and I could do as I pleased—and he had there two piles of bricks, very nice bricks; one pile was of quite smooth, beautiful bricks, the other pile was of the roughest bricks that he could get. I said, "What are you going to do with those bricks?" He said, "I am going to use these rough bricks for the lining and the others for the outside." I said, "Reverse it." He nearly fell off the scaffold. I said, "Won't those smooth bricks make a good lining for the flue?" He said, "Yes, very good, excellent lining." I said, "I am quite sure the other bricks will make a much better-looking outside, and that is the part I am interested in, apart from its drawing qualities." So he put the chimney up wrong side out; and when bricks on the inside cost probably $11 a thousand and those on the outside $6.50; and those he had his scaffold down he said to me, "That is the best looking chimney in this town." The rough hard bricks are the only kind, in my judgment, of which to build a country house, the roughest ordinary hard brick that you can get. I will stand fight with a client on that before I will utilize anything else, because it is the brick with texture and color, the brick that has the burnt head on it, not to be picked into a pattern necessarily, but put there to have its influence on the texture and color of the building. What is true of brickwork is true also of stonework, with us. When we really want to get expensive stone then we get Avondale stone, which is as white as the driven snow and as uninteresting as anything in God's creation; or we use rubbed or sawed limestone, and if not satisfied with the surface being perfectly smooth, we specify that it shall be drove-tooled; when it is generally planed on a machine. Whenever they get the chance to put the machine on and make grooves they do it; and all the texture and sense of stone is gone out of it. For house building the rough stone, the common flat stone that we use down there makes, in my judgment, the finest wall surface in color and texture and interesting light and shade that we can get. Next comes another material, and, in spite of what our friends who like dark exteriors say, I am extremely fond of it, and that is rough plaster, the roughest sort of dashed work or pebble dash. I think that when we are considering the color of the exterior we must remember, as your president said, shadow, the shadow of the cave—make it big if you want to; the shadow of the trees that overhang it, the shadows of the vines that grow on it. What is there more charming, more beautiful than the white cottages and thatched or tiled roofs of England, with their beautiful vegetation around them? We may, perhaps, consign white to a greyer climate than ours, but much of the time we could stand white or nearly white here. And this material, it seems to me, is a very valuable one that is much neglected; it gives us mass, it does not chop the surface up, and it gives us a fine contrast with either stone or brick, whether it be white or colored.

Of course we use a great deal of timber work down with us, and I am sorry to say we very seldom use it honestly, most of our timber work being stuck on the outside of the house and not part of the structure. That of course is inexcusable, there is no possible excuse for it, as far as I can see—I do it myself (laughter), but I am ashamed of it and I am trying to stop. It is almost impossible in this country to use it honestly; I doubt if the timbers will stand in our climate long enough when really built in the wall to make it a practical mode of building.

These are, to my mind, the kinds of material that it is worth while to deal with in house-building. Of course we build wooden houses too. We build shingle houses, and they rot out in from a year and a half to ten years; it is not a permanent building material. We have not used tile roofs nearly so much as we might, that is one of the things that I think the architects here and with us should steadily work for, to get some kind of roof that is not flat, stale and unprofitable like slate, or merely momentary like the shingles of to-day. Tiles are just about as hard to get, but as interesting as bricks or anything else in this machine-made age. I will give my secret away—it may be your secret, too—the only tiles I ever put on a building are the seconds, the culls; they are the tiles that are uneven, rough and crooked and of a good color. The average American selected tile is about as good as red slate, but that is all; as far as texture goes it is about the same. It is worth while, it seems to me, to make a fight on some of these materials that we have to use.

Perhaps the most serious problem we are up against is, how to get this material put together so that it may properly be called architecture after it is done. How much of the building that we are doing in this country would we walk out of our way to see in the old country? or would we collect pieces of as we do pieces of the old buildings? That comes back to the proposition of my friend that the architect is not a designer of buildings, but a designer of opportunities and, if we cannot find the people about us who will seize those opportunities and together with us make architecture, the net result will not be architecture; we will have design but not architecture. Here is where I am going to get "reactionary" in trying to go on straight. People say that we are in a condition, and always have been, of evolution, and that we cannot fight against tendencies. But we know how mankind has evoluted in the past, it has been in spirals. When they were rebuilding a brick Rome in marble they little thought that Rome was in its decline. Their literature, they thought better than the more rugged and rough literature of former days; their architecture they thought better, more refined and elegant; but just the same Rome was in a decline and not on an ascent; it seems to me that it is worth while for architects especially to see what can be done in stemming the tide or at least in diverting the tide from methods that are suicidal as far as art goes. You must remember that

though the body of architects is a very small one compared with the community it has been a very efficient mover of the community. The difference between the Philadelphia—I speak of Philadelphia because it is my own place—of thirty years ago and of to-day is almost entirely due to the few architects who have worked for better things there. They insisted and insisted again and again in spite of the conservatism of client and builder that material and design should be better, and they have bettered them. Now it is in our hands very largely to influence the men who do our work by continually insisting on honest work just as our friend who spoke here on decorative work, assuring us of their willingness to co-operate with us. You will find that these men, who work with you in making buildings, will do exactly the same thing. They may be more stubborn about it, and they have a harder row to hoe than the decorators, for the decorators are more closely in touch with their own work than the builders are. They have the work more nearly in their hands than we have. The men who erect our buildings are divided into two classes, the contractors, with whom we come in touch, and the men who actually do the work. The contractor has, in a large measure, ceased to be a builder; he is simply a contractor; he gets a number of sub-bids, adds them together, and puts on his commission for profit and superintendence, and finances the job, and, to a certain extent sees that it is carried out, that the people working under him carry it out. But he has comparatively little touch and little sympathy with the actual workmen who carry out the work, and they are the men that we must go after. It is not the contractors who have much to do with the actual building; it is the craftsmen, if you can call them that, who do the work.

Now, it seems a reactionary proposition, and possibly a hopeless one, to fight against the machine. Here we are at the end of the 19th century, the century that brags more of its methods of production than any other one thing; and I say that those methods of production are themselves absolutely immoral and reactionary. And I mean it. I mean that the method of production that considers only the amount of the product and the profit that can be made upon it, is absolutely immoral, and that the products of these methods are essentially inartistic, especially in our decorative friends' materials. I know, for instance, what it is to try to select papers for other people; I know that always or nearly always, when the people get the paper on the wall they think you have buncoed them; they will come into the room and say, "That is not the paper I selected, it was not that color, it was not that design." There is a difference between the design, which may be very beautiful and the thing you get upon your walls, wherever it is mechanically made. And that is an essential difference. It is a difference that is bound to exist. I do not care how far you may perfect your methods of production if they are mechanical the result cannot be artistic, because art is, after all, as far as I can see it, only the expression of one's own individuality. Hubbard has said that art is the visible evidence of man's joy in his work. And that is almost a definition, but it is not the real definition, because the art is in the doing of the thing and not in the product of the doing. You cannot, if that be true, get art material or art results without artists. The proof that it is true is that the artist never hoards the things that he makes; his real joy is in the making. The rich people do not possess the art of the country, they have the crumbs that fall from the artist's table, and that is all that they can get of it. The artists are the fellows that get the fun out of it. Art truly is to the artist. Now we architects are only half artists, because while we guide the hand we are not the hand. It is a pity, but it is true. And yet we have the biggest opportunity in the world, and that is the making of ourselves and the crowd better men at the same time, and it is in our hands to do it. We may be really leaders, but the evidence of leadership is a following. If we have not a following among the people that create the things that we are supposed to create then we are in nowise leaders; but we have the privilege of being leaders and educators of the people, and especially educators of our co-workers in making architecture. And how shall we go about it? Of course I do not want to be too savage against machinery and I do not want to repeat what I said last night, but I will repeat just one thing that came up in conversation with Mr. Langton and some others.

Mr. Langton—I think it was too good to be lost by not giving it to others.

Mr. Price—This machinery question is a vital one and one we cannot ignore—as to where we can draw the line on the machine. I was trying to make a distinction, and I think I can make one; I think you will agree that the place where we can draw the line is this—just so long as a machine is a tool with which a man works it is a benefit no matter how highly it may be developed, but the moment it ceases to be a tool and becomes a mere automatic machine into which material is fed, and out of which the product comes without any volition of the man who is working it then that machine becomes an immoral affair, and the product of it becomes absolutely worthless as far as the art world is concerned. That seems to me to be the place to draw the line. That does not cut out band saws or turning lathes, or other power tools, but it does cut out much of the work we have to put up with; for instance, it cuts out machine carving in all its forms. It is an easy way to make a yard or a yard and a half or a whole piece of so-called ornament, but of what value is such ornament. Now can we get the people we build for and the people we build with, to go with us, and return if it be a return, towards a more simple method of construction? I think we can. I think that there is one way we can do it if no other, but it would be a drastic method. That would be to cut off all the ornaments, make the thing absolutely simple and plain with only the essential features in it. Then at least there would be no bad ornaments in it. I think we can go a step further, and instead of cluttering up the inside or the outside of our houses with numberless moldings and brackets and "the Lord knows what, of round and square, stuck here, there and everywhere," without any special meaning except that our ancestors or forefathers did it in marble or some other material, for I am afraid that is the reason we put most of those things in—we can eliminate most of these things and substitute for them extreme honest simplicity in construction, and a little bit of good carving, for we still have the carvers left to us and some of the carvers and decorators are really artists and artisans. I would rather have on my wall a patch a foot square of real decoration interesting enough to go and look at twice than to have the room covered with decoration that has no interest except as to design. That seems to me a most practical line of elimination; cut the quantity of it down to the quick if need

be to get the quality a little where we want it. We can do that, and the people will go with us, for they are just as sick of the uninteresting wall papers and truck that their houses are cluttered up with as we are. I have had no difficulty in getting people to allow me to simplify their houses for them. The tendency to ornament comes from the architect rather than from the client, almost every time. Of course there are exceptions and people want a lot of gaudy ornamentation and display; and I think, in these cases, we had better give it to them, I think that is possibly the best way to cure them. It is a little rough on us, but I think we had better suffer if we can make architecture possible in the doing of it.

I have not talked to you about methods of design. I have not talked to you about what moldings you should put here, there or the other place, I think that would be rather inconsistent since I have been advising you to cut them nearly all out. But what I have been trying to do is to point out certain lines along which we shall design; that we shall in the first place surround the client with a shell that shall be appropriate to its site and its use, that we shall simplify it so that we shall get in the main honest construction and honest ornament so far as we use ornament at all. I think you will readily agree with me as to that question of ornament, when you consider, for instance, the main building of your Toronto University and look at the carving on the inside of it (as I did yesterday with great pleasure), where you can walk along from step to step and find the ornament interesting and worth looking at. That was not the architect's fault altogether. When your president asked me to see it he explained to me very carefully that the architect brought out a real craftsman from Germany or some other place and put him to work there, and he put in those interesting spots. The architect can't do that himself.

The President—I told Mr. Price that the architect was entitled to the credit of bringing him out.

Mr. Price—Yes, you did; but the fact remains that it was the craftsman that did the work. The architect gave him, no doubt, an idea of what he wanted, but like all these things that are worth doing or having, they must be designed in the doing, and not in the lay-out of the doing. You cannot design carving on paper; you can only design carving with a gouge and a mallet. You cannot design wrought iron in any place in the world except on the anvil with a hammer. You can make a suggestion for wrought iron or for carving. You can show the general design or character of it, but you cannot draw it until after it is cut or hammered, because otherwise it is not carving or wrought iron at all. We must recollect that our position is the one that I have pointed out, a designer of opportunities; and what we must do to make architecture a possibility is to go to these craftsmen and ask them, if it be turning back, to turn back; and I think we will get something.

Possibly you are not up against the same difficulties that we are, but this is characteristic of what we have to contend with. Take your carpenter, who is your highest class of craftsman because he does the most varied work, and he will plane and scrape and sand paper the sill of a window and will then proceed to get up on it and stand on his heels to pull nails out above. I do not know whether that happens here or not, but it happens with us. And if the carpenter does not do it the decorator will do it for him.

The President—It is usually the plumber who does things in our buildings.

Mr, Price—The plumber generally does not get as good a chance at it as the decorator; and if he does not do it the man that puts up the curtains and window shades will do it. They are bound to have it in some way. Is it not a distressing situation, that our highest class of craftsmen either do not know or do not care about much except Saturday night's part of their work. It is a pitiable commentary on our civilization that the bulk of our people care for the wage and not the work, because the only thing that is worth doing, in my mind, in the world is work. I am quite sure that the same man, when he gets through working at the job he has to do, if he does not work too long and is not so tired as to kill his ambition, turns to other work. I am quite sure that what Prof. Shortt said about himself is true of most of us, that he gets his recreation by turning from the work he is engaged in most of the time and making furniture, carving and doing such work and he thinks his best thoughts when he is doing so. That our craftsmen should have abandoned that position and accepted the 19th century ideal, that the way to get development is to make the greatest number of things with the least possible effort, or in the least possible time so that he may have time to devote to something else, seems to me suicidal. There is something in work besides wages and a good deal better than wages; and I think we can prove it by simplifying the work, by teaching him that he must do this thing in this way because it is the right way to do it and because it is handsomer when done the right way, as well as more moral and that it will be reflected in his character. But when our work is nearly all sham, as it is in one way or another, how can we expect a man working at that sham work to develop into an honest, straight thinker? He can't do it, and the consequence is he walks on our window sill. I do not want to talk longer about this matter; I would very much rather have a good lively scrap in which we all could join, so with your permission I will stop. (Applause).

DISCUSSION.

The President: I think Mr. Price is a little of an extremist in following the rule of leaving his audience when they still want to hear him. But we cannot ask him to speak too much. I should therefore like to hear the discussion which he proposes we should have.

Mr. Baker: I have much pleasure in moving a hearty vote of thanks to Mr. Price for his very agreeable remarks which I am sure we all appreciated; and I think we all, without exception, agree with him. I feel a little at sea in attempting to say anything as I presume I am expected to do, for I see my name on the paper as leader of a discussion on his address; but if I am able to get around in a circle and back to the place I started from I shall be glad. I am a little helped in starting out by being right in my conjecture as to the line of talk that Mr. Price would give us. I did not expect somehow that he would take up design in the abstract and talk to us about how to put the different parts of the whole design together and that sort of thing; I expected more that he would do just as he has done and give us the moral aspect of it. He has told us that we have got to be teachers. Incidentally I think we have to be learners also, because where we get a client who is a cultured man of understanding and learning and refinement we then find that he is quite capable of leading us in some cases; and we should allow ourselves to be led I take it, as long as we are not led away from practical lines. In thinking this over I came across some lines which were peculiary

apt as being spoken by a man of culture and deep thinking and learning, I refer to Swift; he said:

"I have often wished that I had clear for
life £600 a year;
A handsome house to lodge a friend,
A river at the garden's end,
A terraced walk, and half a rood of land,
saved out to plant a wood."

There is a client after all our hearts. The wish for £600 a year was a modest one. He realized that about that sum would be necessary to live in a handsome house, and wants the means to suit the mansion; that is all. A dignified conception, worth considering by people whose means are fixed but whose ideas of the sort of house they would like are expansive. Our poet's handsome house is what? Not a very great house; not an elaborate mansion full of carving and display; he describes it as a house in which to lodge a friend. He does not want his friend to see magnificent ornaments, but to be comfortable and to have pleasure in spending a time with him. Then he thinks of the surroundings of the house, and, as Prof. Shortt told us yesterday, he makes it fit in with nature. He has the terraced walk and ground for the wood, for he thinks of recreation and wants to get it, as in England, by having a cover for partridges and that sort of thing. That is a man we should like to deal with. Mr. Price would have a happy time with him. We should not need to lead him; he could go with us and we should be favored in going with him. When we get a client who has ideas at all that is what we should do. I recently came across some other lines which are peculiarly applicable to the man who wants the display and magnificence that Mr. Price tells us we have got to give him in order to teach him—it is a sort of homeopathic treatment that perhaps in the end will be effective. Pope had evidently been listening to a long oration of the man who had built the mansion in question and, as he was expected to say nothing, he said:

"It is very fine,
But where do you sleep, and where do you dine?
It is clear, from what you are telling,
It is a house but not a dwelling."

What we have got to provide, I think, for our clients is not exactly what they want most but what they need most, and, if they are vulgar people themselves, that will be what will help them to bring their children up, probably without knowing it, in surroundings of refinement and culture. Mr. Price did not touch on the value of travel in this respect, but I think that that is the key-note of the whole thing. He said that during the last ten or fifteen years the architects of Philadelphia have developed on splendid lines and had improved very much, but I think, if we go to the bottom of the matter, we shall find that, while it is the architects that are the cause of the development, it is the fact that architects have had the opportunity of travel and study amongst the best works of the old lands; that they have come back with ideas broadened and filled out, and have seen the reasons for things that are so hard to see in theory. That I think is the secret of the wonderful advancement that has been made in the art of architecture in the United States, as well as in sculpture and the sister arts. I have seen it written somewhere that during the Continental wars, at the end of the 18th century, or the beginning of the 19th century there was a stationary period in the architecture of England; that there was no advancement but rather deterioration. That was attributed to the fact that continental travel was entirely cut off and the younger generations were not able to go abroad and see the good work that was there. And I think that anything that we, as an Association, can do to send our students abroad, as our cousins on the other side of the line have been doing, by offering scholarships for that purpose, will foster in the surest way the rapid development of design. (Applause).

Mr. Wickson: It gives me much pleasure to second that motion. I am afraid that any remarks that I make will be dreadfully prosaic. I simply wanted to ask Mr. Price a very practical question. We have in our neighborhood some very fine bricks manufactured of a dark color, a very beautiful, dark, varying color, which many of our clients wish to put into their buildings. Following the line that you have suggested, that we try to get texture in our brick work and that the bricks should not be too smooth and that sort of thing, we would rather lay bricks in honest mortar; but from my own personal experience I find that these dark bricks which are so much admired, and which are good serviceable bricks as well as good looking bricks; if laid in ordinary mortar do not give a satisfactory effect. It seems almost impossible to get anything like a clear joint—I do not mean a small joint but one which is not ragged—are we justified in coloring the mortar to make it look well?

Mr. Price: I should judge you were justified in doing anything you pleased about coloring the mortar, although it might be possible that you would lose the sense of surface, which you would readily do. I should say that if you must color the mortar, it would be well to do it in such a manner as not to disguise the joints; simply as a question of preserving the texture of the brickwork. Of course much of that effect can be accomplished by slightly raking the joint so that you get a natural shadow on the joint itself, thereby modifying its color.

Mr. Reid (Ontario Society of Artists): I should like to ask Mr. Price if he would color plaster on the outside of a building, since color in the plaster seems to be a way to arrive at an effect.

Mr. Price: I can see no reason at all why we should not color a plastic material of that kind. We color them with us in various ways; some that we call natural and some artificial. The natural way is to color them by using sands of various colors; and that is the best way, because that color is an integal part of the mortar itself and if chipped off or broken can be patched again without disadvantage. Whereas the using of ground colors has this disadvantage that patching is almost impossible. I can see no reason why you should not color mortar just as much as any other surface, any other plastic material on which you wish to get color and texture. I should think however that that color should always be mixed in, not applied, because the tendency of applied color is to destroy the texture.

Mr. Simpson: There was one thing that struck me in Mr. Price's paper. I cannot remember in detail all that interested me, I hope to read the paper and refer to it often in our Proceedings; I should like to have it indelibly impressed on my mind. There is one thing that I should like to draw attention to now. When Mr. Price was speaking of building according to what our owner's requirements are, it occurred to me how architects allow themselves sometimes to be influenced by the owner's whims that are not really requirements and are not in accordance with good taste. I have noticed that architects have sometimes been afraid of their clients and afraid to speak their minds out. We must distinguish between this and the sympathy with their ideas of which Mr. Price speaks. I am sure we all feel very much indebted to Mr. Price and will be greatly benefited by his remarks.

Mr. J. P. Hynes, (Architectural Eighteen Club): I should like to express my appreciation of Mr. Price's paper or lecture; I feel that it is the most complete thing I ever ran across. In speaking of the texture of materials: Philadelphia has been somewhat of an experimental ground I think for that and I would like to hear what Mr. Price would have to say in regard to the way in which, in the Museum of Natural History of Pennsylvania, they have experimented not only with the color of brick but the size of the joints and mortar Many of us have seen it, some have not. I considered it one of the most interesting pieces of brick work I had ever seen. But I doubt if it is an experiment I should try.

Mr. Price: There is no criticism to make of the brick

work there except on one point and that is that, to carry out their original scheme of a long brick, (I never heard why they could not or did not get it) they bound two bricks together with a fine joint between them. That is of course an essential dishonesty, and a great drawback from a building that is, apart from that, very simply constructed and beautiful. That peculiarity does not shew up in the photograph very well; for one reason because it is only a fragment. You have there a pediment with an entrance door, which is practically but a porch to the main building, with a flat dome back of it, and it naturally looks severe; but the texture of the building is prefectly charming. The bricks are a dark and rather heavy brick, and the mortar is a cement gravel mortar, with three-quarters of an inch thickness of joint, and laid up

Corner Dome of Varied Industries Building, Louisiana Purchase Exposition, St. Loius.

slightly back of the face; that is, it is not a raked joint exactly but it is pushed in as well as they could. They have added a large amount of color work to the building through by introduction of mosiacs in brick and terra cotta and marble and stone; anything at all that would give them the color effect. There is no sham about it as far as I know, unless you choose to call the color of the marble a sham. The marble they use is treated with iron, which rusts it and makes permanent stains. It may be questionable whether that is proper or not, but we should be all very glad if our marble in conjunction with brick work were so unfortunate as to have a nail driven in just above it and became rusted naturally. They have only gone one better than that; and it is probably a color that the marble would get with extreme age.

Mr. Mortimer: What is the size of the brick?

Mr. Price: Ordinary brick, about 8½ inches.

Mr. Hynes: I notice that where they used moulded brick it did not seem to have as satisfactory a result as where they had used other brick in a pattern; a kind of a frieze, with a row of headers under, which is all that marks the change from the wall to the frieze. In other places there is a row of projecting headers which are bullnosed and (particularly as the lines of the brick work are not very good with this heavy joint in it) it seems inappropriate to mould the brick; to put a moulding on something in which a virtue is made of roughness. While the variegation of brick work was kept on the surface it was very satisfactory indeed. I thought one lesson might be drawn from that building and that is to leave moulded brick alone. It was, however, only where the moulded brick projected past the surface that it did not seem to be satisfactory. Where they kept it in the surface, as headers, it seemed to be very effectual as decoration. I do not know whether Mr. Price would agree with that or not.

Mr. Price: I should agree with it very largely. Moulded brick of course is very dangerous material, because the essence of the building is that it shall be a long line and the essence of the brick is that it is a short chunk which tends if made too much of to destroy the long line. Much of the best mouldings of that work are not moulding at all but projections which give a shadow and do not pretend to be mouldings. Besides the moulding is smoother than the rest of the brick and gives a difference in texture.

Mr. Helliwell: In common with those who have spoken I would like to express my appreciation of the paper we have just listened to and at the same time

congratulate the Committee, who had charge of the arrangement of our programme, because there has been such a variety of subject and topic. We have had the structural part very well brought before us, and this afternoon we have had this other feature. In connection with the address we have just listened to, I should like to say how fully I fall in with the idea of the importance of house architecture, in this way, that, while comparatively few architects have the privilege of dealing with monumental buildings or even with very large and expensive commercial buildings, there are no architects who have not the opportunity of dealing with the domestic subject. Another point too is this:—when Mr. Price was speaking of the part that the artistic had in the production of architecture, and in connection more particularly with the use of material in its common state, such as brick of the coarse stamp; it struck me that this coarse texture, one of the beauties of that kind of material, depends more on the way in which it is put in than on the material itself. Take for instance these bricks of which we have heard, the mottled or multicolored brick; there are instances in our city, known to us all, where these bricks have been used and where the effect is not altogether pleasant; where we have a rather speckled or spotted effect; there are cases, on the other hand, where the bricklayer, in using this brick, has exercised his judgment and taste in working the brick together in such a way that the effect is beautiful. This is one of the instances in which I think we can see the advantage and great importance, if we are to have the best kind of results, of the craftsman himself entering into the feeling of the architect and the idea which is sought.

Mr. Burke: That very point came home to me very closely when I was building my own house; I had practically to educate the bricklayers. I went down to the brick yard and saw a pile of culled bricks there that the brick manufacturer said came off the arch of the kiln. I said, "Those are the bricks I want." I had a great deal of trouble getting sufficient to do the work because the bricklayers were rather wanting to throw out the roughest bricks; they wanted to get the bricks all the one color. Whereas I did educate them to understand that they should just take the pile as it was; not to deliberately put a black brick against a yellow brick, but exercise a little judgment. They took the run of the kiln. With regard to the chimney Mr. Price spoke of I had the very same experience; I had only just enough brick left to finish my chimney; and the hod carrier said, "We have not any bricks." I said, "Yes, there is a pile there." "Oh, he said those are all knobby bricks; great big knobs on them; they wouldn't do at all." I said, "Take them up." And I think I have one of the prettiest chimneys in Toronto in consequence. Regarding the question of design in connection with the steel framed buildings I think Mr. Price struck the right note there, that the cover of the steel should be a plastic cover. Then comes in the question how to make our plastic covering agreeable to the eye. We all know of course that Portland cement has not an agreeable color and it is practically impossible to make it agreeable. It seems to me then that we should get a plastic material with an agreeable color; and what more agreeable color could you think of then tiles; carefully made tiles or tiles of suitable color? Should not this, then, be the future of the steel framed building covered with plastic material?

The President: We cannot close this discussion up in the absence of Mr. Price who has been called out of the room to speak to some one and we will have to converse among ourselves as he is unfortunately speaking to a friend outside. The principal difficulty about molded brick is always that a molded brick is out of scale and it is difficult to get any scale for a building with molded brick because the horizontal size is too small. I was very interested in a point that has been spoken of by other speakers; in the way Mr. Price proposes that we should look at the point of view of our uncultivated client. He likes something and it is a bad thing, but what he likes is not necessarily it's badness; and what we have got to turn our minds to is to find out what is the good thing in it that he likes and we can appropriate. The client who admired the building on 49th Street evidently was a Philadelphian who had had enough of the old fashioned Philadelphian work — two windows and a door, with marble lintels, downstairs, and three windows, with marble lintels, in upstairs; a pressed brick front; and what pleased him was the life he saw in the inverted arches on 49 Street. It is quite possible to fiet the idea that he wants some life; to avoid the monotony which he wished to avoid, without perpetuating bad art. If a client likes bright color it is possible to give him bright color without giving him crude color. I was glad when I heard Mr. Price was coming to speak to us because it is impossible to see any representation of Philadelphia work or hear anything about Philadelphia without perceiving that there is a great deal of life there; and I thought we should get some life. We have certainly done so. Mr. Price has demonstrated that although the pen is mightier than the sword the tongue is mightier than the pen. I think if we could have him a little more amongst us we should soon be strongly infected by the spirit which is in the air now, and nowhere, I think, more than in Philadelphia. I am glad to see such a meeting as this, it could not have occurred fifteen or even ten years ago. The public are getting interested in art. If we could have a little more of Mr. Price—we shall have a little more of him when we read the Proceedings. We shall do a great deal to bring about what Mr. Hughes said at lunch about having an ideal and bringing our environment into harmony with that ideal. I have much pleasure, Mr. Price, in presenting to you the vote of thanks.

Mr. Price: I should just like to acknowledge the extreme pleasure I have had in being here with you, especially in being able to be with you through the entire session. I doubt whether it is possible to speak intelligently to people that you do not know, any more than to build houses for people that you do not know; but if there has been anything in the few rambling remarks that I have given that have been good for you I feel quite confident that you yourselves have brought it out by your sympathy.

At the Louisiana Purchase Exposition the building of the State of Washington is to be in the form of an octagonal tower 114 feet high. The framing is to be all of wood and the main members will be eight diagonal timbers resting on the foundations and meeting in an apex. Each timber will be over 90 feet long and 24 x 28 inches in cross-section in one piece.

How Greater London grows is shown by the annual report of the Chief Commissioner of the Metropolitan Police, who gives a return showing the number of new houses built and new streets and squares formed, with their length in miles and yards, during the past year. There were 27,174 houses built, 301 new streets formed, occupying a length of 60 miles 408 yards, whilst the number of new houses in course of erection was 6,449. There was just over 2,000 more houses built than in the corresponding period of the previous year. Since 1891 the number of new houses built number no less than 1,812,127, the number of new streets made being 8,643, and seven squares, the length of such being 531 miles 206 yards.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The Association met in Annual Convention in Montreal on January 22nd, the President Mr. Joseph Venne, presiding. Among those in attendance were the following:—Messrs Joseph Venne, W. E. Doran, A. T. Taylor, A. Raza, J. P. Ouellet, L. Lemieux, L. A. Amos, M. Hogle, S. Lesage, Charles Bernier, A. Chausse, Alph. Venne, J. Carmichael, J. S. Archibald, D. A. Brown, Professor S. H. Capper, Raoul Lacroix, A. Sincennes, G. R. Gardiner, H. C. Stone, and L. Z. Gauthier.

The work accomplished by the Association during the year is set forth in the report of the Council as follows:—

REPORT OF COUNCIL.

GENTLEMEN,—The proceedings of your Council for the year just closed may be summarised thus: (a) Lectures and monthly meetings reorganized. (b) Library. (c) Professional Progress and Education. (d) Legal proceedings. (e) Public competitions.

LECTURES—In accordance with instructions given by last year's general meeting, the Council arranged for monthly meetings of the Association, and endeavoured to give to these meetings a social as well as an educational character. The attendance warrants the belief that these gatherings have proved useful to members.

It was not deemed advisable to make a special arrangement for such meetings during the summer months from May to September. As will be seen below, the subjects arranged for these meetings are of an extensive and varied character, the desire being to interest as many members of the Association as possible.

March:—The series was commenced in March with an illustrated lecture on "Electric Wiring" by Prof. R. B. Owens of McGill University, which was numerously attended, the Council having the satisfaction of welcoming a large number of gentlemen interested in the subject outside of the membership of the Association.

April:—A lecture on "Westminster Abbey" by Prof. S. H. Capper, fully illustrated.

October:—At the October meeting a discussion took place on "Professional Esprit De Corps."

November:—The first of a special course of three lectures on "Architectural Jurisprudence," by Mr. S. Archibald, Advocate.

December:—A reception was given to Mr. L.P. Hebert the sculptor, to which members of the Royal Canadian Academy and other artists, both painters and sculptors were invited. The reception was followed by an interesting discussion on "L'Art Nouveau", illustrated by lantern views specially prepared for the occasion.

The remaining lectures on Architectural Jurisprudence will be given in February and March and the special committee, who will continue the organization of these meetings, will doubtless arrange for further subjects of interest for the following months.

MR. W. E. DORAN,
President Province of Quebec Association of Architects.

The Council would point out to the Association that the success of these gatherings wholly depends upon members themselves and the interest they continue to take in them.

Library:—This year the use made of the Library has shown progress. The only additions to the Library have been the usual periodicals; this has been more especially due to the fact that it has been considered necessary to provide an electric lantern and screen, etc., to be used in connection with the lectures.

Professional Education:—In view of the preliminary suggestions submitted to the last annual meeting, and in pursuance of the instructions formulated at that meeting, the Council appointed a Committee, which reported at its regular monthly meeting of June 16th, 1902.

Meetings of the Association were called in July and again in August, to consider this report; but on neither of these occasions was there a quorum of the Association present. The report will, accordingly, be presented at the meeting this year.

Legal Proceedings;—Legal proceedings were taken during the year against one architect who was practising illegally with results favorable to the Association; but, owing to difficulties (more especially of form) in the matter of these legal proceedings, the Council obtained additional legal advice, which should enable the succeeding Council to proceed more expeditiously, by minimizing complications which have hitherto caused delay.

Public Competitions:—The Council, in accordance with the principle already adopted in the past, that public works should be offered to competition, provided such competition be conducted on well recognized and equitable conditions, took advantage of the proposed public library for Montreal to appoint a deputation which waited on the Mayor, in order to urge that this library, in common with other public buildings, be submitted to public competition between architects in good standing of the city, and that a professional adviser be appointed to report upon all competitions. The deputation met with a very favorable reception, and your Council have every reason to hope that this reasonable request will be acted upon.

Examinations:—At the January examination Mr. L. T. Bristow was registered as student, and at the July examination Mr. Rene Charbonneau was registered as student and Mr. J. W. Gregoire as Architect.

ATTENDANCE AT THE MEETINGS OF COUNCIL. 18 meetings.

J. Venne	President	Montreal	14
W. E. Doran	1st Vice-President	"	7
R. P. Lemay	2nd Vice-President	Quebec	..
Prof. S. H. Capper	Secretary	Montreal	14
J. S. Archibald	Treasurer	"	18
G. E. Tanguay	Councillor	Quebec	..
A. Raza	"	Montreal	11
A. C. Hutchison	"	"	4
A. A. Cox	"	"	8
S. Lesage	"	"	9

It is to be noted that Messrs. G. E. Tanguay and R. P. Lemay, being from Quebec, could not attend the meetings.

The Association now numbers 118 members.

Members Deceased;—The Association has to record with regret the death of three of its members during the past year: Mr. V. Roy, past-President of the Association and a distinguished member of our profession in Montreal; Mr. H. R. Falbord of Montreal; and Mr. J. B. Verret of Sherbrooke.

JOS. VENNE, President.
S. H. CAPPER, Secretary.
MONTREAL, January 7th, 1903.

QUEBEC SECTION REPORT.

On the 17th December, 1901, the Quebec Architects elected their officers for the year 1901-1902. Mr. R. P. Lemay was re-elected President of the Section, and Mr. Jos. P. Ouellet, was reelected Secretary and Treasurer.

The Quebec Architects have this year begun to compile by-laws for building construction in the City, which they hope to have adopted by the Municipal Council. They have elected for this purpose a Committee, composed of Mr. R. P. Lemay, President, Messrs. F.-X. Berlinguet, W. D. Baillargc, Thos. Raymond, and Jos. P. Ouellet, to study the by-laws in force in the sister cities of Montreal and Toronto, in order to adapt from the by-laws of these two large cities all that seems practical for local requirements.

The Committee has not yet reported, because the City Council of Montreal and Toronto are themselves amending their own by-laws; and a copy of such revised by-laws will be addressed to the secretary at Quebec as soon as the work is done.

The election of officers resulted as follows:—President, Mr. W. E. Doran, Montreal; First Vice-President, Mr. J. P. Ouellet, Quebec; Second Vice-President, Mr. J. S. Archibald, Montreal; Secretary, Prof. S. H. Capper, Montreal; Treasurer, A. H. Lapierrie, Montreal; Council, Messrs. A. Raza, D. R. Brown, J. Carmichael, J. E. Vanier, Joseph Venne, Montreal, and E. H. Stavhley, Quebec.

At the afternoon session the newly elected President presided. The Educational Committee's report contained the following important suggestions and recommendations:—

"1. That it is timely for the Association to create a scholarship of architecture covering a complete course for the benefit of students bona fide residents in the province of Quebec, and who are employed in the office of a regular member of the Association;

"2. That such scholarship should be for a complete course to be taken for the present at McGill University, as said university is the only one having to this date equipped and organized a complete course of architecture;

"3. That the selection of the beneficiary should be made by competition, the first competition to take place about September 15th, 1903.

"4. That such competition be conducted by a board of examiners composed of three representatives of McGill and three

members of the Association, appointed by Council, with an additional member from McGill as president;

"5. That for the present, and until further change by authority of the Association, the successful competitor for said scholarship must undertake to follow the full four years' course of architecture at McGill.

It is further suggested:—"1. That members be invited to present, either collectively or individually, artistic and professional scholarships under such conditions as they may think proper and as may be acceptable to the university;

"2. That members should select by preference their help from students at the university; further, that some might see their way to make arrangements with students in their offices so that, for the help given by such students outside of the regular season and hours of a college course, the employer might pay the fees of such course. Further, that the university might possibly consider the feasibility of so arranging the hours and even the courses that students might follow the course and attend an office co-ordinately;

"3. That a circular embodying said propositions may be issued to members;

"4. That honorary members be invited to create a travelling scholarship for regular students having graduated and taken their degree in architecture at the university, that such scholarship should be administered by the university authorities in conjunction with the Association, under such rules as may be framed. That such travelling scholarships should be called the "Travelling Scholarship of the Province of Quebec Association of Architects Honorary members,' or such title as may be determined upon."

Professor Capper in referring to the report expressed the opinion that the Association having assumed responsibility under its charter for the qualifications of architects practising within the Province, was also under obligation to do something towards the proper education of the students.

Mr. A. T. Taylor reminded the members that it was largely by suggestion of the Association that the chair of architecture at McGill University was established, yet the Association has so far contributed neither money or students to the support of the movement.

The report was adopted, the Council instructed to take steps to give effect thereto, and power to modify the details with regard to clause 4, referring to the scholarship at McGill.

On motion by Mr. Venne the Council were authorized to take steps to provide a suitable home for the Association.

The following resolutions were also adopted.

By Professor Capper and Mr. A. T. Taylor, F.R.I.B.A.:—"That the Province of Quebec Association of Architects, while desiring to facilitate access for all classes of the community to the park on Mount Royal, protests against any scheme which would destroy the natural beauty or impair the integrity of the mountain as a public park, and detract from its present woodland character."

By Mr. Taylor: "That the Association instruct the Council to press anew upon the attention of the City Council the great desirability of constituting an artistic advisory committee to confer with them on all matters affecting the beauty and amenity of the city."

By Mr. Venne:—"That the Province of Quebec Association of Architects, having at heart the preservation of our ancient mounments, strongly protests, in its character as an artistic profession against the additions that have been made to the Chateau de Ramezay, on the ground that these have seriously impaired the antique character of the building, without any countervailing gain on its artistic or utilitarian side."

It was decided that the next annual meeting of the Association should be held in the city of Quebec.

THE ASSOCIATION DINNER.

The Association have reason for congratulation that their annual dinner, given in the Place Viger Hotel, on the evenng of January 22nd, was such a marked success. It might not perhaps be quite correct to call this function an annual dinner, the last being held in '98, but there are reasons for believing that in the future it will become an annual event. The attendance this year numbered upwards of fifty. Apart from the members of the Association those present as guests were the Hon. Lomer Gouin, provincial minister of public works; Mayor Cochrane; Mr. L. M. Symons, President of the Ontario Association of Architects; Mr. Amos, representing the Canadian Society of Civil Engineers and the representative of the CANADIAN ARCHITECT AND BUILDER. Several members of the Association from Quebec city were present.

One end of the handsome dining room had been set apart and tastefully decorated for the occasion. The tables were arranged in horse shoe shape, the floral decorations being very attractive. The menu was tastefully designed, being printed in white and gold, the front cover bearing the Association seal and the back the names of the officers of the Association.

Between the different courses, orchestral music was rendered and after the cigars were lighted speeches were given by the members and the guests, interspersed with songs and musical selections. Every feature of the occasion had evidently received careful attention at the hands of those in charge, and the function was on the whole exceptionally satisfactory. The President, Mr. W. E. Doran, presided, having on his right, Mayor Cochrane and Mr. Symons, and on his left the Hon. Mr. Gouin and Prof. Capper, of McGill University. Before proceeding with the toast list letters of regret were read from the Lieutenant-Governor, the Hon. Mr. Sutherland, Hon. S. N. Parent, Sir William Macdonald, Mr. R. B. Angus and Senator Drummond. After the health of the King had been enthusiastically toasted, Mr. Doran in an excellent speech, proposed "Our Profession" and in the course of his remarks urged that the proposed Carnegie public library should be placed on such a site as would somewhat inspire the architect instead of being placed in cramped quarters such as have been suggested on St. Lawrence street, where there was little room to make use of elegance of design, such as the character of the building demanded. He claimed that the architectural profession had so far been largely ignored regarding this matter. This had too often been the case in the past; too often the ideas of the architect were unappreciated. Though the world is filled with enduring monuments of the past centuries, the architect's connection with their existence is too little remembered excepting when he has perhaps made a great blunder. There are exceptions to this, of course, as in the case of Michael Angelo's success with the dome of St. Peter's and Christopher Wren's creations in England. The public is always too willing to say of the architect, "Earth lie heavy on him as he has laid many a load on her." The architect, certainly, when he makes a mistake, is pretty sure to hear of it afterwards. Quite different is he in this respect to the physician. As the speaker told a member of the latter profession recently: "When you make mistakes they get below ground but when we make mistakes they remain above." Mr. Doran proceeded to show how broad an architect must be to fill the many requirements which are to-day demanded of him. He must be an artist and have grand conceptions, he must have the practical knowledge to enable him to oversee the workman, he must be a business man and a lawyer, and at the back of these and many other requirements he must be a man of strict integrity. The speaker then outlined the preparation which a man studying for the profession must make and paid particular attention to Canadian conditions and requirements, ending with an announcement regarding the new travelling scholarship spoken of elsewhere in this issue which has just been established. This toast was also responded to by Messrs. A. Raza, Jos. Venne and W. Carmichael.

"Kindred Associations" was proposed by Mr. J. E. Vanier in a pleasant speech in his native tongue. This was responded to by Mr. Symons, President of the Ontario Association of Architects. Mr. Symons stated that he was greatly pleased to be the bearer of greetings from the sister association in Ontario. Architecturally, he said, Montreal is surely a city set on a hill. Speaking of the Quebec Association, he stated, that its charter was a most excellent one. In this respect he considered the Quebec Association was in advance of it's sister associations in the other provinces. The privileges granted the P. Q. A. A. should serve as a precedent for legislation in Ontario. He looked forward to the time when there would be one Association for the whole Dominion. He expressed himself as being pleased to see so many young men present; it augured well for the Association that the young men should take so much interest in the proceedings. He was greatly pleased with the city and contrasted it favorably with Toronto. Montreal had a great advantage in having stone and other material near at hand in which to earnestly, faithfully and truthfully erect enduring monuments which for centuries would be a joy to look upon. In closing, Mr. Symons in behalf of his Association thanked the Quebec Association for the reception accorded him.

A. Chausse, architect and building inspector of the city, was called upon and spoke briefly. Prof. Capper gave a short reading. Mr. Vanier proposed "Our Guests," and this was replied to by Mayor Cochrane and Hon. Mr. Gouin. The Mayor referred to the new library which has been a live issue of late and pointed out the great advantage of erecting it upon the St. Lawrence site which belonged to the city and would take nothing from the $350,000 promised by Mr. Carnegie, leaving that amount entirely at the disposal of the architect. Mr. Gouin made one of the best speeches of the evening.

Songs were given by Mr. Labelle accompanied by Prof. Capper on the piano. The last toast on the programme "The Press," was proposed by Prof. Capper in a humorous and interesting address, and was responded to by Mr. A. B. Pickett on behalf of the CANADIAN ARCHITECT AND BUILDER.

Before rising from the table Mr. Archibald, in a witty speech, proposed the health of that individual whose modern skeleton steel framed structure, covered with rock-faced, grey limestone front, contained a high pressure boiler in the shape of a good warm heart, heated by the fires of interest in the Association— in other words, the President, Mr. W. E. Doran. This toast was most enthusiastically honored.

The function closed with the singing of God Save the King and Auld Lang Syne.

Mr. Wm. Hutchinson, Chief Commissioner for Canada to the Louisiana Purchase Exposition accompanied by Mr. Wm. A. Burns, Secretary of the Exhibition Department of the Department of Agriculture at Ottawa, recently visited St. Louis for the purpose of selecting a site for the Canadian pavilion, and to arrange for space for the Canadian exhibit.

The Prussian Minister of Public Works has issued a recommendation to use bricks of large size in monumental buildings, and in order to ensure that they are made in sufficient quantities and at reasonable prices he places the sizes at 28.5 cm. long, 13.5 cm. broad and 8.5 cm. deep. This is the size of the bricks to be used in government buildings. The joints are to be 1.5 cm. A metre is to be counted as ten bricks.

Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

NOTES.

The Bridgeport Wood Finishing Company's calendar for 1903 shows illustrations of the laboratory factories and offices at New Millford, Conn.; mills at Branchville, Ct., and offices in New York, Philadelphia and Chicago.

The next convention of the National Association of Builders will be held in the city of St. Louis during the year of the World's Fair. Preference was expressed that the convention be held in the month of February of that year, although the exact date was left to the discretion of the Executive Committee.

Boston, it is alleged, is indulging in the elevator girl. It is time to call a halt, says the Baltimore Builders' Journal. We are taking too many risks. We do not question the willingness nor the intelligence of the girls who may run elevators, but we should have neither elevator girls or boys. We should have men, and good robust men at that. In case of accident or fire a great deal depends upon the courage and strength of the person in charge of the elevator.

NORTHWEST LETTER.

WINNIPEG, Feb. 12, 1903.

In giving you a resume of the work in course of construction, in my letter some months ago, I stated that I would give a description of the finished work in this letter.

Of all the large work that was commenced last year such as the Strathcona Block, St. Mary's Academy, St. Stephen's Church, etc., the Canada Life Building is the only one that can be said to be in any way completed. The alterations and additions to this building has entailed a very great amount of unusual work in the way of underpinning. Great credit is due the contractors, Messrs. Illsley & Horn, for the workmanlike manner in which they carried this out. Although they were handicapped in several ways, such as strikes, scarcity of material and labor, they completed the whole work in the space of seven months, which is an extraordinary short period for this western country. The whole of the walls of the ground floor on the street fronts was taken out and rebuilt in Bedford stone, an operation which required the most careful handling and which was finished with the thermometer registering somewhere between 20 and 30 below zero. This work was done alter the remainder of the building was completed, and which therelore necessitated the carrying of the four floors above. The Canada Life will occupy the main portion of the ground floor, the upper portion of the building being laid out as a modern office building.

In looking into the prospects of work for the coming season, it seems almost incredible that the sum of $4,000,000, as given in the daily papers, is to be expended. I have made numerous enquiries as to the authenticity of these figures and find it impossible to arrive at a total in any way approaching this amount. If, as it is reported, this amount of work is to be proceeded with this year it means that there will be a deadlock in all branches of the work before the season ends. A famine in both material and labor will be the result. During the past year, with the small amount of work done, compared with the figures given, there was a paucity in the supply ot all kinds of material and to obtain labor of any description was most difficult. This was most noticeable in the demand for Portland cement and building was stopped in numerous instances on account of the scarcity of this material. Oak is another commodity that cannot be had at the present moment except in very limited dimensions. To remedy the conditions of the supply market immediate steps should be taken by contractors and others to accelerate the shipping of supplies from outside.

In order to be able to successfully cope with larger work, a number of the most prominent contractors of this city have formed themselves into a supply construction company. This company with a membership of twenty-five, more or less, will include members of all trades and the most prominent ones, generally speaking, in each case. The forming ot a company of this description is, I think a very doubtful proposition, and whether Winnipeg will benefit by it is very much a question. It will no doubt be a monoply to a great extent of the building trades and the successful working of such a scheme as this is a matter of conjecture.

In looking forward to the large work, contractors are reserving themselves from tendering on smaller work, and it is now a difficult matter to obtain tenders on such buildings. Work that has been tendered on shows a great increase in the cost of building compared with last year and all branches of the work were then extremely high. It is rather hard as yet, the contractors find, to determine the prices of either material or labor and on account of this enough has to be allowed, and in figuring they must allow on the right side.

Of work that has been mentioned as probable to start this spring the Union Bank, the Bank of British North America and the Canadian Pacific Railway station are among the largest. The Union Bank is to be a ten storey building with steel construction and fire proof throughout, the plans of which are now being prepared by Messrs. Darling, Pearson & Over. The Bank of British North America will be much smaller, being, as I understand, only three to four storeys in height. The plans of this are now being prepared by Mr. Andrew T. Taylor, F.R.I.B.A., Montreal. Several large warehouses are to be erected this year, the plans of which are now in the hands of local architects. Some of these warehouses will cost in the vicinity of $50,000.

A competition has recently been held for the Winnipeg Carnegie Public Library, and although I do not wish to expatiate on this matter I would like to place before you some of the facts relating to the conditions: The cost of the building, including architects' fees and all permanent fittings, was fixed at $75,000. Three premiums were granted: $300 (which was to be included in architect's fee if work was proceeded with), $200, $100. A special committee of the Council of the City of Winnipeg has awarded the premiums. Eight sets of drawings were sent in, all of them being in the opinion of the Council most creditable. The drawings are not yet on exhibition and the only ones I have seen are those of the successful competitor, Mr. H. S. Griffiths, who kindly allowed me to see his design. He regretted that he was not in a position to allow his design to be published until alter he had received tenders, which close on the 24th inst., for if the total cost of the work exceeds the amount specified in the conditions, the work is placed in the hands of the next successful competitor. In plan, Mr. Griffiths has, I think, been very successful and the working of the library should be most satisfactory. In his elevations, however, he has I think been a little too severe and a little more elaboration would have improved the elevations much. He has promised to permit his designs to be published in the March issue of your paper and I will then forward them on to you. It is rather regrettable regarding the criticism and awarding of the designs, that it was conducted under such adverse conditions. It is a well-known fact that the "man on the street" knows practically nothing about the true principles of architecture, and for a body of such men to undertake the criticism and placing of the competitive designs in their order of merit makes the result of the whole work a deplorable fiasco. It seems lamentable that the commissions for such public buildings should be so often granted in this hopeless manner. Of course it may be said that this form of procedure is often adopted and a precedent thereby instituted, but strenuous efforts on the part of architects should be made whereby the criticism of such drawings would be placed in the hands of some competent arbiter. The method employed in this case was as follows—Each plan was submitted with its non-de-plume, which, by the way, an alderman stated was a dissimulation, as he understood the names were known to some of the members of the Council. After several meetings of the Council was held and serious consideration given to the various drawings, they announced that to them the drawings all looked so much alike that they were incapable of determining on any special set. A meeting of the whole city Council was therefore convened to act in conjunction with them and to again discuss the relative merits of each design. The result of this proceeding was that the Council voted on all the drawings and the five most favored were again handed over to be dealt with by the special committee, who accordingly finally determined on the three best.

The mistake made I think, was that when the special Committee found that they were incapable of making a choice between the drawings they did not call in some experienced, capable and thoroughly unbiased authority and thereby obtain an equitable and satisfactory decision.

I notice in the daily press that an offer has been made by Mr. Carnegie to Toronto of a large sum for the erection of a similar building to the above. If this is accepted and a competition held a more satisfactory arrangement than the above, it is to be hoped, will be arrived at.

I intended forwarding to you photograph of the Canada Life Building, but have been unable to get this in time for this issue.

W. PERCY OVEN.

Practical Capability

ISN'T THAT THE NECESSITY IN BUILDING MATERIALS?

Most experienced builders all over the country use our

Sheet Metal Building Materials

Because they are honest, capable goods, unstinted in quality, that give the acme of artistic effect as well as sterling endurance.

We make every conceivable need in Ceilings, Shingles, Sidings, Lathing, Finials and Architectural Adornments.

Familiarity with our Catalog is a liberal education in the subject of building requirements.

METALLIC ROOFING CO.,
Limited
TORONTO MONTREAL WINNIPEG

PUBLICATIONS.

A new work entitled "Letters and Lettering," by Frank Chouteau Brown, has been published by the Bates & Guild Co., Boston, Mass., price, $2. It comprises 200 pages bound in cloth and contains a treatise on lettering, with two hundred examples.

"Common-Sense Handrailings and How to Build them," is the comprehensive title of a new book for the practical man from the ten of Mr. Fred. T. Hodgson, author of numerous well-known practical books for the building trades. The book contains three distinct treatises, each complete in itself and is liberally illustrated with working diagrams explanatory of the text. Price, $1.00. The publishers are Messrs. F. J. Drake & Co., Chicago.

"Wall Paper and Wall Coverings," a practical handbook for Decorators, Paperhangers, Architects, Builders and House-owners," by Arthur Seymour Jennings, editor of the London "Decorator," etc. One large 8vo. vol.; cloth. Price, $2. New York: Wm. T. Comstock.

The book which is liberally illustrated, treats of the seslection of wall papers, varieties and characteristics of papers, tools and methods for hanging, etc.

The Amherstburg Quarry Co. have sent out a calendar showing views of their quarries and shipping facilities.

BUSINESS NOTES.

To meet the demand for a varnish which will give a smooth, hard finish and enhance the beauty of the surface upon which it is applied and for general purposes, the Canada Paint Company have introduced the universal "Sun" Varnish. It is said to have been made from selected clear bright gum and every tank thoroughly matured and tested before being put into tins.

The Don Valley Brick Works are about to install a plant for the manufacture of porous terra cotta fireproofing material. Messrs. Bowman and Miller representing the company recently had an interview with the members of the Toronto Chapter of Architects to learn what sizes of blocks would best meet the requirements for partitions and arches. The consensus of opinion was that for partitions the sizes most in demand would be 3 and 5 inches and for arches, 8, 10 and 12 inches, with skewbacks to suit the various sizes of beams.

The attention of Canadian architects is called to the announcement appearing in the advertisement columns of this number regarding the R.I.B.A. examinations. The Canadian architects who succeeded in passing the examinations last year were Messrs T. McLaren, Arnott Woodroofe and Chas. Hopson.

work were then extremely high. It is rather hard as yet, the contractors find, to determine the prices of either material or labor and on account of this enough has to be allowed, and in figuring they must allow on the right side.

Of work that has been mentioned as probable to start this spring the Union Bank, the Bank of British North America and the Canadian Pacific Railway station are among the largest. The Union Bank is to be a ten storey building with steel construction and fire proof throughout, the plans of which are now being prepared by Messrs. Darling, Pearson & Over. The Bank of British North America will be much smaller, being, as I understand, only three to four storeys in height. The plans of this are now being prepared by Mr. Andrew T. Taylor, F.R.I.B.A., Montreal. Several large warehouses are to be erected this year, the plans of which are now in the hands of local architects. Some of these warehouses will cost in the vicinity of $50,000.

A competition has recently been held for the Winnipeg Carnegie Public Library, and although I do not wish to expatiate on this matter I would like to place before you some of the facts relating to the conditions. The cost of the building, including architects' fees and all permanent fittings, was fixed at $75,000. Three premiums were granted: $300 (which was to be included in architect's fee if work was proceeded with), $200, $100. A special committee of the Council of the City of Winnipeg has awarded the premiums. Eight sets of drawings were sent in, all of them being in the opinion of the Council most creditable. The drawings are not yet on exhibition and the only ones I have seen are those of the successful competitor, Mr. H. S. Griffiths, who kindly allowed me to see his design. He regretted that he was not in a position to allow his design to be published until after he had received tenders, which close on the 24th inst., for if the total cost of the work exceeds the amount specified in the conditions, the work is placed in the hands of the next successful competitor. In plan, Mr. Griffiths has, I think, been very successful and the working of the library should be most satisfactory. In his elevations, however, he has I think been a little too severe and a little more elaboration would have improved the elevations much. He has promised to permit his designs to be published in the March issue of your paper and I will then forward them on to you. It is rather regrettable regarding the criticism and awarding of the designs, that it was conducted under such adverse conditions. It is a well-known fact that the "man on the street" knows practically nothing about the true principles of architecture, and for a body of such men to undertake the criticism and placing of the competitive designs in their order of merit makes the result of the whole work a deplorable fiasco. It seems lamentable that the commissions for such public buildings should be so often granted in this hopeless manner. Of course it may be said that this form of procedure is often adopted and a precedent thereby instituted, but strenuous efforts on the part of architects should be made whereby the criticism of such drawings would be placed in the hands of some competent arbiter. The method employed in this case was as follows—Each plan was submitted with its non-de-plume, which, by the way, an alderman stated was a dissimulation, as he understood the names were known to some of the members of the Council. After several meetings of the Council was held and serious consideration given to the various drawings, they announced that to them the drawings all looked so much alike that they were incapable of determining on any special set. A meeting of the whole city Council was therefore convened to act in conjunction with them and to again discuss the relative merits of each design. The result of this proceeding was that the Council voted on all the drawings and the five most favored were again handed over to be dealt with by the special committee, who accordingly finally determined on the three best.

The mistake made I think, was that when the special Committee found that they were incapable of making a choice between the drawings they did not call in some experienced, capable and thoroughly unbiased authority and thereby obtain an equitable and satisfactory decision.

I notice in the daily press that an offer has been made by Mr. Carnegie to Toronto of a large sum for the erection of a similar building to the above. If this is accepted and a competition held a more satisfactory arrangement than the above, it is to be hoped, will be arrived at.

I intended forwarding to you photograph of the Canada Life Building, but have been unable to get this in time for this issue.

PUBLICATIONS.

A new work entitled "Letters and Lettering," by Frank Chouteau Brown, has been published by the Bates & Guild Co., Boston, Mass., price, $2. It comprises 200 pages bound in cloth and contains a treatise on lettering, with two hundred examples.

"Common-Sense Handrailings and How to Build them," is the comprehensive title of a new book for the practical man from the ten of Mr. Fred. T. Hodgson, author of numerous well-known practical books for the building trades. The book contains three distinct treatises, each complete in itself and is liberally illustrated with working diagrams explanatory of the text. Price, $1.00. The publishers are Messrs. F. J. Drake & Co., Chicago.

"Wall Paper and Wall Coverings," a practical handbook for Decorators, Paperhangers, Architects, Builders and House-owners," by Arthur Seymour Jennings, editor of the London "Decorator," etc. One large 8vo. vol.; cloth. Price, $2. New York: Wm. T. Comstock.

The book which is liberally illustrated, treats of the selection of wall papers, varieties and characteristics of papers, tools and methods for hanging, etc.

The Amherstburg Quarry Co. have sent out a calendar showing views of their quarries and shipping facilities.

BUSINESS NOTES.

To meet the demand for a varnish which will give a smooth, hard finish and enhance the beauty of the surface upon which it is applied and for general purposes, the Canada Paint Company have introduced the universal "Sun" Varnish. It is said to have been made from selected clear bright gum and every tank thoroughly matured and tested before being put into tins.

The Don Valley Brick Works are about to install a plant for the manufacture of porous terra cotta fireproofing material. Messrs. Bowman and Miller representing the company recently had an interview with the members of the Toronto Chapter of Architects to learn what sizes of blocks would best meet the requirements for partitions and arches. The consensus of opinion was that for partitions the sizes most in demand would be 3 and 5 inches and for arches, 8, 10 and 12 inches, with skewbacks to suit the various sizes of beams.

The attention of Canadian architects is called to the announcement appearing in the advertisement columns of this number regarding the R.I.R.A. examinations. The Canadian architects who succeeded in passing the examinations last year were Messrs T. McLaren, Arnott Woodroofe and Chas. Hopson.

Government Building Designs by Competition.

It is gratifying to learn that the system recently inaugurated in the United States of procuring designs for government buildings by limited competition among architects of the first rank in private practice, has proved entirely successful. So satisfactory have been its results that it is proposed for the future to include in such competitions public buildings of less importance and cost than those to which the Tarnsey Act was originally intended to apply. With such a precedent before them the Federal and Provincial Governments of Canada should adopt the system in this country. The result would be that Canadian architects would be stimulated to put forth their best efforts, and variety and interest would be imparted to government buildings throughout the country, such as many of the existing ones do not possess. Again, the influence of a number of well designed public buildings scattered throughout the length and breadth of the Dominion would react beneficially upon the general architecture of the country. Why do not the Architectural Associations of Ontario and Quebec earnestly take up this matter and persistently press home upon government the advantages of the competitive system.

Municipal Art Commissions.

The Art Commission of the city of New York is a pronounced success and a lesson to other cities. During the past year they gave an opinion (not always favourable) upon fifty-five sets of plans for different structures; and, as the President of the Commission says in his report, the plans disapproved have been amended or perfected so as to "show a marked improvement, concurred in as such by the original designers." The Commission's principal power is only the power of veto; but that is final, and, as designers do not want to run up against it and be turned back to amend their drawings, the consequence is (to quote the President again) that "greater care is being taken in the preparation of designs than ever has been the case." In other words the old idea is upset—that anything will do for the city; that it is not design that counts but pull. All this is the work of ten gentlemen whose services on this commission cost the city nothing. It surely is worth the while of other cities to get an art commission appointed without delay. Sodom and Gomorrah are not the only cities that ten righteous men could save. No doubt the dread of putting so much power in any one's hands has hitherto been deterrent; but the evidence of New York's experience goes to show that this fear is groundless; that human nature tends to rise to what is expected of it; and that an art commission in whom trust is really reposed will be really trustworthy. The New York Art Commission has the confidence of the community. When the commission declined to allow the old Tweed County Court House to be extended to within a few feet of the City Hall, and so ruin the City Hall Park, public comment was "if we had had the Art Commission earlier we should never have had such a monstrosity as the County

Court House at all." The Commission is a power in the city. Simply by execising it's veto, it kept the committee for the Soldiers' and Sailors' Monument marching about for a site, disapproving of one after another, until the present admirable site on Riverside Drive was found. It has kept numberless unsuitable structures from being erected in the Plaza, to the injury of Central Park. The Commission works. When shall we see something of the sort in Canada? Here is the composition of the Art Commission of New York: The Mayor; three permanent officials, viz.: the Presidents of the Public Library, of the Metrupolitan Museum of Art and of the Brooklyn Institute of Arts and Sciences; three representatives of the three professions of architecture, painting and sculpture; and three gentlemen specified to be not members of any profession of the fine arts. We have at least half a dozen cities in Canada in which a similar body could be selected without difficulty.

The Basing Unit in Concrete.

Mr. Charles M. Crawford, of the Hartford (Conn.) Paving and Construction Co., in a paper, which was read before the Connecticut Society of Civil Engineers, and published in a recent number of the Engineering Record, demonstrates the importance of more accurate definition than is usually given of the basing unit in cement concrete. Mr. Crawford cites the specification for an important public improvement in the State of New York. This specification reads:— the "concrete . . . will be proportioned: — one part by volume of Portland cement; eight parts of volume of aggregate of stone, gravel and sand." The question is, how is the volume of the unit of Portland cement to be measured—in the barrel or out of the barrel? A barrel of cement is the usual unit of volume; but a barrel of cement has two volumes — one in the barrel and one out of the barrel.

Mr. Crawford quotes test measurements of barrels, in which Portland cement of different brands had been packed, as ranging from 3.24 to 3.59 cubic feet; but the volume of the cement, when loose, is greater. Tests made for himself established the weight of a cubic foot of Atlas Portland cement, loose, at 91.27 lbs., making a barrel (380 lbs) equal 4.16 cubic feet. Here is a difference which has a serious bearing upon the question of cost.

Take the smaller measurement. If the "one part by volume of Portland cement" be taken as 3.25 cubic feet, the aggregate will be eight times as much, or 26 cubic feet. Of this 40 per cent., or 10.4 cubic feet (which is about the proportion of the voids), will be sand and 60 per cent., or 15.6 cubic feet will be stone; and the mixture will make about 16 cubic feet of concrete.

If the larger measurement, 4.16 cubic feet, be taken for the barrel of Portland cement;— there will be 33.28 cubic feet of aggregate, composed of 13.31 cubic feet of sand and 19.97 cubic feet of stone; and the mixture will make about 21 cubic feet of concrete

---

The cost of these two operations—with cement $1.50 a barrel, sand 60 cents a cubic yard, and stone $1.50 a cubic yard—will, in the first instance, be $4.37 a cubic yard, without labour, and, in the second, $3.74; a difference of 63 cents a cubic yard. We have made the calculation from prices said to have been in force when the work for the specification in question was let. As cement has since gone up in price, the difference now would be even greater. But taking 63 cents as a possible difference in the cost per cubic yard:—as the work covered by the specification in question amounted to about 90,000 cubic yards of concrete, the sum involved in a difference of opinion as to the volume of the basing unit would be, as Mr. Crawford says, "worth considering."

P. Q. A. A. Scholarship.

It is rather remarkable that the well endowed and equipped department of architecture at McGill University should still lack students in spite of the fact that examination is the only way to the practice of architecture in that province. The Province of Quebec Association of Architects have considered it incumbent on them in order to make the benefit of the architectural course felt, to create a scholarship both entitling and compelling the winner of it to take the full four years' course at McGill University. This is no doubt a move that will in time effect its object. The first student who wins the scholarship and takes the course will of course be snapped up by a good office, and then it will begin to become apparent to the rest that something has happened which makes the architectural course desirable. If immediate advancement comes to two or three students who have taken the course, it will become a necessity. A distant view of himself either the better or the worse for having or not having a good professional education it is not easy to bring before the mind of a young man, but he can see immediate consequences; and it ought not take long to fill the architectural lecture rooms of McGill with students, if it is once demonstrated that to have passed the course gives the student an immediate success that can be measured in terms of dollars and cents as well as of opportunity.

A further proposition was made, as an additional suggestion, in the same report of the Educational Committee of the P. Q. A. A.:—that "some (members) might see their way to make arrangements with students in their offices so that for the help given by such students outside of the regular season and hours of a college course, the employer might pay the fees of such course." This in common with the rest of the report was adopted and "the Council-instructed to take steps to give effect thereto," but this is a proposition that requires careful handling lest it do more harm than good.

The thing to be borne in mind, in offering inducements to architectural students to do their studying thoroughly, is that the inducements must be inducements to work, to take the profession seriously; not inducements to enter the profession as the softest thing going; and it is a question—if education is provided, for the mere consideration of filling out the year in an architect's office (which the student would do anyway if he were obliged), for want of this kind offer, to get his training entirely in an architect's office)—it is a question whether the profession of architecture in the Province of Quebec will not have

the greatest claims to popularity with an undesirable class; that class of young men who, with a sort of general capacity in some degree but with no decided bent, are ready to be attracted by incidental attractions in any of the professions. If electrical engineering continues to require a long apprenticeship under the orders of mechanics, while architecture offers a university education free of charge, the usefulness of electrical engineering as a limbo for the vaguely aspiring sons of vaguely aspiring parents, who would otherwise aim at architecture, will be gone; architecture will excel in popularity but its chances as an art will be proportionately diminished.

The same doubt hangs over the proposition to create a travelling scholarship. As stated in the Educational Committee's report the proposition is that only "regular students" who have graduated and taken their degree in architecture at the university "shall be eligible for the scholarship." That is an excellent proposition; but the motion to adopt gives the Council "power to modify the details with regard to clause 4," which is the clause relating to this scholarship.

It is to be hoped the Council will not attach this scholarship to anything less than a full career in arts and architecture at McGill. Then we shall feel sure not only that it is in the right hands but that the process of getting it is too long—requires too much decision of mind towards this career and too much hard work—to attract triflers. It is attraction that is principally to be feared. The actual winner of a scholarship may be of the right stuff but, unless the scholarship is so hedged by conditions of preliminary service that it colours the prospect with visions of work rather than with visions of foreign travel—for every trained and travelled student the profession gains, we shall have another or possibly more whom the chance of free foreign travel has enticed to desert a career of usefulness to others and profit to himself in "business."

THE EFFECT OF HIGH PRICES ON BUILDING.

Attention is being called to the manner in which the demands of workmen in the building trades coupled with the high prices of materials, is checking building enterprise in Toronto.

Notwithstanding the all-round advance in wages last year, several of the unions have already decided to demand a further substantial increase. The plasterers for example, are asking 45 cents per hour, an advance of 7 cents. It is understood to be the intention of the plumbers to demand 65 cents per hour; the painters have also demanded an advance while at the same time they have voted down the request of the employers to be allowed three instead of two apprentices to each shop, and that the term of apprenticeship be extended.

In view of these demands and the uncertainty as to what the scale of wages will be, contractors feel obliged to protect themselves against loss by a substantial increase in their tenders. This has already resulted in blocking considerable work which, had prices remained about the same as last year, would have gone forward to completion.

The opinion prevails that the point has been reached at which any addition to the cost of either materials or labor will prove to be the last straw which will break the back of many building enterprises. This is a particularly unfortunate condition when money is plentiful, and under favorable circumstances would be largely invested in new buildings.

Investors in buildings must keep in mind the possibility of a return of less prosperous times, when if their buildings have cost too much the shrinkage in values may entail upon them a loss. Thousands of owners found themselves in this position on the collapse of the real estate boom in Toronto several years ago.

Some large commercial undertakings may go on in spite of higher prices, but many smaller ones, especially residences, will be stopped. This means a few large contracts for a few large contractors and employment for a few hundred workmen, leaving idle a much larger number of both masters and mechanics.

Workmen give as a reason why they should have more pay that the cost of living, including rents, has greatly advanced. They apparently do not see that this advance is largely due to their constant and ever increasing demands for more wages and shorter hours, and that as they comprise the bulk of the consuming class, they are themselves called on to bear the heaviest part of the burden. This was clearly demonstrated by the recent coal strike, the effects of which were felt most severely by mechanics and laborers. This strike has probably permanently increased the price of coal in this country. In the case of articles of general consumption such as fuel, the use of which cannot be dispensed with, the future policy of the producing companies will probably be to cease fighting against higher prices in behalf of the consumers from whom they get no thanks, and to accede to all demands of their workmen and charge up the extra cost to the consumer. Who is the consumer? In seven cases out of ten he is the wage earner, the man who is least able to bear the added burden.

In the case of the building industry, the conditions are somewhat different, but the result is much the same. People are not obliged to build expensive residences—they can live in the old ones, take rooms in an apartment house or an hotel, or adopt other modes of living which are at least less expensive and freer from care than the management of a modern house. So it happens that when prices of materials and labor reach a certain point, building enterprise slackens, the demand for materials falls off and the mechanic in the building trades and in the factory is thrown out of employment. All of which goes to show that it is possible to kill the goose that lays the golden egg, and also that to do so is a very short-sighted and unwise proceeding.

In joining parts of metal and glass by means of plaster of Paris, a serious source of trouble (according to "Werkstatt") is the tendency of the plaster to set and harden before a proper cementation has been attained. This can be easily prevented by adding to the water with which the plaster is mixed 6 per cent. of alcohol. Then sufficient time will be allowed for cementing before complete hardening occurs. Too much alcohol must not be used, otherwise the plaster will not harden.

COLOGNE CATHEDRAL.

BY THE WAY.

In the opinion of the Irish Builder Chubb's new patent front-door latch, with very small key, is an extremely handy, up-to-date idea. The Club man who may have occasion to use the very small key has yet to be heard from.

× × ×

Towns like individuals frequently refuse or neglect to profit by experience. A case in point is the town of Liverpool, Nova Scotia, which, although fire swept only seven years ago, has again been almost wiped out of existence by fire.

× × ×

A prominent bank president of Hartford was having his house repainted recently. To him entered a caller, who said:—"Do you know that your house is being painted by non-union men?" "Yes," was the answer, "I took particular pains to find them. Get out!" That is all the story, except that the house is painted.

× × ×

Colonel Butler, a former Sessions Judge in Burma, and retired, happened to be an artist and has painted some very pretty scenery as well as birds and flowers in the Japanese style on the walls of the Maubin Court House in Lower Burma. It forms says Indian Engineering, a pleasing contrast to the generality of such buildings, though we fear the minds of accused persons committed to the Sessions are too much occupied with other thoughts to appreciate pictures, however artistically they may be depicted.

× × ×

A British contemporary tells a good story of an old lady passing by the scene of the demolition of the famous old Newgate Prison in London the other day, when she espied the contractor's enormous steam crane. Appealing to a wily crossing sweeper, said she, "Can you tell me my good man what is that for?" "That 'laidy,' says the wily one, "that is the famous gallows you must have often heard of. Aye, 'laidy,' many's the sickening sight I've often witnessed on that 'ere 'gallis'—take away yer appetite for breakfast—'twould," and as he wiped his eye and pocketed the two-pence; reflected that it was well earned.

× × ×

A curious action at law is said to be pending in connection with what is known as "The flat Iron Building" on Broadway, New York. The owner of a store opposite this building is said to have brought legal action to compel the owners to reimburse him for the breaking of his plate glass windows by currents of wind alleged to have been deflected from the slanting walls of the "flat iron." The plaintiff alleges that pedestrians have been thrown to the sidewalk by the wind while passing this building, and that in consequence they now avoid the locality. He proposes to secure the testimony of such persons as well as of architects and other experts in support of his claim.

THE EDUCATION OF APPRENTICES.

A series of lectures to masons' apprentices were given last winter by members of the Illinois chapter of architects, and were so successful that it has been decided to continue them during the present winter. The master masons and the masons' union have arranged an apprentice system under which each apprentice receives three months' schooling each year, during which time he is obliged to attend school and also receives his pay from his employer.

The Inland Architect states that the city of Chicago has also arranged school-rooms and teachers for their special use, and their studies not only comprise elementary branches, but follow such technical lines as will best serve them in their work. It is encouraging to note that of the apprentices who attended school last

PEOPLE'S BANK OF NEW BRUNSWICK, FREDERICTON, N. B.

winter not one seemed indifferent, and many attended the night as well as the day classes, and all were enthusiastic and diligent. This has all been accomplished by the unselfish work of a few men who wish to aid in the elevation of the workman and the improvement of his work, and shows what can be accomplished in every trade, and how gladly such aid is accepted by the young mechanic who wishes to succeed in mastering his trade.

The Engineering Record states that the lettering of titles and important legends on drawings is expedited in the drafting rooms of the Bureau of Filtration, Philadelphia, by the use of standard letter sheets about 11x14 inches in size upon which are printed five standard alphabets and sets of numerals in plain Gothic type. These sheets also contain words most frequently occuring in titles and other places printed in the size of letter most frequently used for them. In this way a great deal of time usually spent in spacing is saved, for the draughtsman can slip one of the standard letter sheets under his tracing and copy the words needed.

ARCHITECTURE AS A SOCIAL ART.*

Prof. Shortt: Mr. Chairman and Gentlemen: I come before an architectural organization with a great deal of diffidence, because I cannot say that I am even an amateur in architecture, but simply a much interested reader on architectural subjects, and much given to the observation of buildings and other products of architecture, and of the allied arts. I had written out my paper, but from the nature of the questions with which I wished to deal, and which were mainly suggestive, I thought it was rather too stiff, and looked altogether too important for the matters I had to bring up; I wish, therefore, the members present to understand that what I am throwing out is simply a series of suggestions with reference to some problems which have presented themselves to my mind. In considering the subject of architecture as a social art, the question arose, Whence came this art? What forces have determined its growth and what is its significance for the public at the present time? You will see, therefore, that the line which I am to take is not one which concerns itself with the technical aspect of architecture, but rather with its relation to the people. Each art has its special votaries who understand its details, its principles, and so on; but these arts, and architecture above all others, have a special significance for the public. Therefore, the question arises, how did the public come to be interested in architecture, and what is its significance for them?

Now, in this respect it seems to me that architecture, in common with several other arts, is not on the basis of most of the sciences, and particularly not on the basis of a science such as mathematics. The determination of the artistic or proper features of architecture are not to be worked out as we work out the fact that the three interior angles of a triangle are equal to two right angles. When we have discovered that proposition we have discovered something that was eternally true and will be true for all times. When we have discovered a principle in art, it does not necessarily rest upon the same basis, for it may be modified very greatly as time goes on; and the problem, therefore, which I have set before myself, and on which I wish to make some suggestions is, Whence arose this feature of architecture, and what is its significance? It seems to me that here we are face to face with a problem that is incident to the beginning of human interests. What were those beginnings? They were connected with the fact that man had to make his own way on this earth, that is, they are connected with the struggle for existence.

I say the foundations of architecture are associated with the foundations of man's living on the earth. Self-preservation, therefore, is the fundamental feature. At first sight it may seem strange that self-preservation should have any connection with architecture, yet the connection is quite real and vital. When we come to consider what it is that has built up mankind, his interests, his senses, and his feelings, what we discover is, that the stimulus has followed two lines:—the seeking of that which is favorable to the race, and the avoiding of that which is unfavorable or destructive. There is a common myth abroad that the beginnings of human interests were individual, that the struggle for existence is the struggle of the individual to maintain itself. That is not a fact, as can be found by investigations all the way back through man and the animals too. The instincts that are registered in humanity and the animal are instincts for the preservation of the race. Another false conception is that the pleasurable feelings are associated with preservation and the painful feelings with destruction, Now, as a rule, pleasurable feelings are associated with preservation and the maintenance of existence, and many of the painful feelings with destruction, but not all. And I think that none of our secondary interests would be maintained, or would indeed have existed had only the pleasurable feelings been developed. Thus, we find that, going no further back than the savage, when we ask what it is that is registered in primitive man, what is his interest in this, that and the other thing, we find it due to that minute and careful study of nature forced upon him by the avoidance of his enemies and the pursuit of his prey. Thus, the accurate knowledge which the savage acquires from his close study of the bent twig or the crushed leaf, of the trail of the various animals and of all nature's conditions, is the outcome of ages of specialization in which he has had to attain to accurate experience of these before he ever waked to a secondary interest in them. Thus the eye was not formed to see beautiful colors, or fine forms, or anything of that kind; the eye was formed as a concentration of a certain nervous structure in the body for self-preservation; and so with the other organs which in lower animals are simply diffused feeling, but in the higher animals, and in man particularly, are aggregated into special senses with special functions for preservation; but there comes in connection with them the secondary satisfaction in succeeding, and the horror of failure which is associated again with the preservation of the race. Again we notice in the domestic animals as well as in wild animals, that when an animal has not its full capacity drawn upon in the pursuit of prey, in the avoidance of enemies, or in its other functions of life, it simulates the familiar process, and the animal plays at that which is its life-work. And you will notice that the wild animal and the domestic animal not only take pleasure in stimulating joyful feeling, but they alarm and strike terror into each other, taking interest in developing that side as well as the other: thus the comedy and the tragedy of life are remotely born in man and are there before they ever come to a conscious condition at all. But eventually man relates these things to a purpose. He acquires an interest in life that is not merely that of incidentally obeying instincts, but that undertakes to take hold of these and make something of a purpose in life, within the spiritual continuity and unity which is expressed in humanity; that spiritual unity is the one great feature of humanity, not the elements that it unites. The elements that it unites are animal elements, the senses and physical needs. But it is the spiritual unity that gives them meaning, that first of all takes these elementary purposes and moulds them into some connected view of life. Now the first phases of that connected view of life, as we see, are associated with the interest in the secondary features of animal life. It is there that the significance of the arts for human life comes in. How is it that man should come to unify any of the feelings connected with the senses along an artistic line? What is the force behind the expression? Well, it is usually a force connected with awe and fear, rather than with immediate pleasure. An art whose products are associated with the awesome, the fear-inspiring, emphasizes the threatening aspect of existence which most arrests human attention. That which falls in with our everyday needs, and satisfies these needs, passes unobserved; and thus it is we take more interest in the failures of life than the successes, in a way; therefore, primitive man in his aspiration is more actuated by fear than by pleasure. All primitive religions, also modern savage religions, are connected with the worship of evil spirits much more prominently than with the worship of good spirits. And why? Because man wants to propitiate the evil spirits and escape them; and consequently his first worship is entirely sacrificial. Anything that will appease these spirits is the proper thing, and that is characteristic of all savage and barbaric people in the spiritual line. This feeling is hidden deep in human nature and expresses itself in the child,—you all have had experience, no doubt, of some sort of terrible creature, suggestive of a bear, a tiger, a dragon, or other fearsome thing that is apt to inhabit the dark recesses of an ordinary domestic home, being apt to go upstairs behind you or come out of a closet and attack you. That is simply the unconscious expression of what has been rooted and grounded in the savage nature of man for ages; and the time between savagery and civilization is so short that it can't be got rid of; thus the child reproduces many of the things that its savage ancestor most feared. What is the significance of that for architecture and art in general? It is, that in order to give concrete expression to his feelings, in order to afford these vague beings a definite worship, man undertakes to give form to associations, to construct fetishes and other grotesque objects of worship, which, at first, are of the most vague and uncertain character, but are afterwards given an architectural clothing or housing. Thus, we can find to-day all the phases of this from what goes on in the central tepee, the public and religious tent or structure of the savage, right up to our Government Buildings and cathedral churches. We can find it not only historically up through the ages, but contemporaneously through different peoples at different stages. All these features then, associate themselves with this art, the first effort of the savage to embellish the tent which houses his religion and his politics. The common council house, which is at once the centre of the medicine man's activity and the councillor's oratory, is specially built and ornamented and rendered symbolic. Domestic architecture is a mere reflex from that, but has no great interest in it. This same feature which is the basis of architecture is associated at an early time, in the case of our own institutions and those of the Greeks and Romans, with ancestor worship, and the perpetuation of the idea of immortality. Consequently, the first temples are also, as it were, the first tombs; and the tomb-temples of Egypt, rock-hewn structures, are the beginnings of much of the higher architecture of the country. There is a link here that has been lost to us, because the first structures were usually made of the material at hand, perishable material: wood, clay, brick, and so on, colored and decorated with totems and things of that sort, which express in these grotesque forms the aspirations of the people. Those are swept away or eaten up by the tooth of time. Only when we come to rock-hewn temples or structures carved or built up out of stone do we get anything that persists through the ages. And, as you architects all know, when you come to examine these structures you find they are reproductions, even the finest Greek temples, of wooden-built structures; structures erected of beams, timber and posts; that is their essential character, but they are in many cases very elaborately modelled and ornamented, raising the simple elements to a higher degree, as it were, by an elaboration of them in a large temple. When you take, therefore, the construction of the Egyptian temple, you find the oldest of them and the most remarkable express above all things mystery and fear rather than beauty. Yet there is a beauty in them, too. There is the obvious aspiration of the human spirit; the feelings of the men who raised these temples are wrought into them, and their interest in nature is also expressed, for though the work be crude in technique, it is exceedingly accurate and living in the spirit of it. That is, they show themselves, before they have got the technique, to be able to appreciate the fine things in nature. Even primitive creations that are dug up, the scratchings of animal forms on bones, shells, and so on, while rude and crude most of them, are essentially accurate with reference to nature, and show that their authors were still very close to nature. I omit, in order to get on, the Assyrian and Babylonic fragments, and come to the Greek temples, which in so many ways resemble the Egyptian, and what do we find there? We find a higher expression; we find less of the fearsome or awesome, less of crude mystery and more of intellectual beauty. Why is that? Because the Greeks in their rapid development had come to understand nature at large more fully than the Egyptians, had come to understand that there was less of the blindly threatening aspect in it, and more that could be understood and appreciated. With a rising sense of beauty the Greek spiritualized his architecture; he turns the Egyptian temple inside out, and instead of clustering all the columns inside to make it dark and mysterious and threatening, he puts them outside and ornaments them, while he expresses in the interior simplicity itself. Altogether the structures expressed a civic and a religious feeling which showed the real core of the civilization of the Greek. Concurrently with these beautiful structures come the other arts which are all the children of architecture. Painting, sculpture and all these things came as accessories of architecture, not as things developed on their own basis and put into architecture. But as civilization advances, becoming more complex, these things come to be separated from architecture, and have an existence of their own. Thus, at a later stage, pictures are not painted merely for mural decoration, but for interest in the subjects separately,—they can be carried about and hung up here and there to be seen; and so with statuary and music, and a good many other things which were all associated with religious and social art. I use these terms religious and social as interchangeable. When we go back to early society we find there is no difference between the religious and the social aspects of it; their politics were religious, and their religions were political. The embellishments of the temples and meeting-places were all connected with this one social structure, because individualism was something that was to be developed at a later stage.

Thus, we find that all the great original architecture is social;—there is little or nothing that is

*Paper read at the annual convention of the Ontario Association of Architects held in Toronto January 13th and 14th, 1903.

original or important in domestic architecture; it is simply the reflex of the ideas that were carried out in a larger scale and in an original degree in the social and religious architecture.

When, however, we come to the Roman we begin to note the separation, the development of a style of architecture that was more domestic and an application to it of original features, as is shown in the Pompeian remains, and that was partly due to the fact that the old Roman religion had gone to decay. The features of individualism creep in and change the character of architecture. The Roman architecture is the first, it seems to me, which shows a wantoness, which no longer expresses the purity of an aspiration. The buildings often lack high character and chastening purpose. Thus, there is the application of ornament merely as ornament. Now, that never was shown before; it was ornament subordinated to the great purpose of the temple or the structure.

The next great movement that I want to touch on in this connection, is the development of architecture through the Christian church. We come back, through the Christian church when it had dropped its individualism, and got to be a unified church, to a great organization with aspirations of a high order. Under the church the Roman Empire again took the lead of civilization, both socially and religiously. There we get a structure that calls forth once more all that is great in man; and once more it finds visible expression in architecture. The domestic habitations at the time of the building of the great cathedrals were poor things, attracting little attention; and the castles and keeps were for strength, and if strength were got, ornament or any higher aspect of architecture was largely neglected. There was indeed a secondary influence coming in afterwards from the religious side, which rendered these feudal keeps and castles more artistic and architectural. But the great cathedrals of Europe once more expressed in themselves thorough appropriateness and great human interest. There you see once more that no sacrifice, no artistic ability, no power that can be suggested, is too great for the realization of this idea; and therefore, they built as well and as nobly as ever they possibly could; but in doing so they were doing just what the primitive savage had done in setting up his council house, in ornamenting it and associating his life with it. But from the time of the great religious structures we come to a condition of things which, as soon as we strike the decay of the religious feeling—not at the Reformation, but before the Reformation—is very mixed once more. Take the Renaissance movement in Italy, and you observe the revival of an interest in art for art's sake, which in the absence of other inspiration is a very dubious standard; thus there were produced some very good things and some quite monstrous things. Again we come back to the suggestion in the decadent Roman architecture. People are ordered to put up buildings by some great civic or church authority, and they are ordered to ornament them in certain ways; not for the glory of God, but for the expression of human magnificence. In that they may run to all sorts of extremes, and thus we have the vagaries that are committed, even though they are checked and corrected by those who have a purer and larger conception of their art. Even amidst the corruption of the period there were those who began to develop standards of art for themselves, and to look at art as a conscious spiritual expression. However, from that time down, we see all manner of vagaries and all kinds of mixtures for the reason that western civilization was breaking up into self-conscious fragments. The further down we come and the more utilitarian man becomes, the more completely does he get at sixes and sevens in his architecture. The best part of it for a time really comes to be semi-domestic, namely, the mansions of the great feudal lords, now a landed aristocracy, who took a real interest in their feudal domain, and who wished to raise these worthy structures of theirs, great domestic castles and baronial halls in England and France and other places, which would be worthy of their power, of their position in society and the state.

Thus once more we notice that these things are, if I may use the expression, owned of nature. That is largely after all what gives such a marvelous attraction to some of the great country houses in England? It is their complete unity with their setting, with the surroundings, with the character and life of the people at the time, and that is the only true standard, I think, in the end.

I shall have cause to refer to that again, because I think we are coming back to that, and it is one of the hopeful signs of the present; but what I have to notice first is the very mixed era that comes between the great cathedral-building period and the present day, when people's ideas seemed to be so much at sixes and sevens, and the utilitarian spirit prevailed, the spirit which put up a structure to serve a purpose and thought any kind of a building was good enough. Some people, however, had further ideas. They seemed to say to themselves that it would be just as well to ornament that building, to give it a more graceful form, or something of that sort. Thus they came to apply ornament in an external and dead sort of a way to a building erected, with no aspiration that demanded the ornament, or that determined that this kind of ornament can be used and the other kind cannot; or that this atmosphere and this setting demands certain things, and that situation is utterly inconsistent with certain others. And thus we get those monstrosities in architecture where you have no end of work often, and great expense, but extremely little effect, or a negative effect. Coming down to our own country and applying some of these tests, what we find is the development nowadays of the imitative, the merely imitative feature; certain things in this building are admired, and other things in that building are admired, and the party who admires them seems to think it would be a good idea to combine these things together and make a structure of some sort; and thus we get freaks. The dwelling house is frequently designed as a very costly affair, and apparently no thought is given to the situation, the climate, or anything else in the appropriateness of the parts. The result is sometimes congruous, by matter of accident; and sometimes quite incongruous both in its interior and exterior, and in its setting. That was the characteristic feature of much of the architecture of America during the past century, except for people and architects who came over from Europe, and in the first generation produced here and there things that had some feeling and setting.

I have been very much struck with that in Ontario. In going about the Province I have come across houses with grounds attached where there

was clearly some attention paid to the location and the surroundings to make lite harmonious within and without. And when one comes to enquire why this was done, and why it has gone to delapidation since, one commonly finds that it was due to somebody who came out from the old country, quite frequently with no architectural ideas at all in the technical sense, but having been brought up amidst beautiful surroundings, having their appropriateness ingrained in them, wished to reproduce in some measure a similar setting in their surroundings here. But the second generation, not having been brought up in the same atmosphere, fell away from the old standards and allowed the place to go into decay. Many of these picturesque old places are decayed up and down America as well as Canada; and it is only recently that our architects have been waking up to the fact that there is something in appropriate combination. Now, out of that I wish to draw the further fact, which is so important in the social aspect of our subject, that architecture of all the arts is the most constantly educative, and it is educative in the very best and highest way, namely, in the way in which the savage was educated. Architecture is a constant presence, and when good it develops taste and appropriateness in the minds that respond to it, without any effort, simply because they come daily in contact with it. Let the mind be situated in any other region and it will have no such aspirations, as is shown in this very fact of the first generation being interested in realizing the ideas which they unconsciously received in a better surrounding, and the second generation neglecting them altogether. Later on we come to the development of wealth. Go out into the country and find a man who has made money as a farmer, and who decides to put up a house. When he looks about his farm for a location for that new house where does he put it? You can find by going through the country. He looks through the farm and says, "It would be a pity to spoil that field, it is a good wheat field; it would be a pity to spoil this other field, it is good pasture; but there is a rocky waste piece that has never produced anything; if I put my house on that it won't destroy any of the farm." He puts his house on the most miserable place on the farm, and that is commonly the end of it. If he goes any farther, he will, perhaps, put in a tree or two, one hedge of evergreens, beginning half-way back on the house, and coming down to the gate, and he may not even trim them. Now such a man has traveled away from contact with nature, he has been in a region in which the utilitarian factor alone has been dominating his soul; he has none of the spontaneous aspirations of the first men; he has none of their vivid religious fervor and feeling, but he is dominated by what will distinguish him among his fellows, and his house is a visible emblem of it.

Architecture must be social in the end, and even in a region where a man puts up a house such as I speak of, his wealthy neighbors catch the idea and they put up houses like it and treat them in the same way. Go up and down country roads and you will see the same type reproduced over and over again. It is difficult for the architects, and I am sure you sympathize with yourselves in that, to get a man to see that there is more in architecture than merely displaying his money, and keeping a kind of Holy of Holies, as some of them look upon it, in the front of the house which the owner enters on Sunday, when he gets his best clothes on. He goes in there and sits down in a stiff attitude, quite uncomfortable, passing a day there, because you have to occupy the room somehow, and Sunday is the most appropriate day for occupying it. That is partly what has dominated this country, but we seem to be coming to a better era, and it seems to come of the development of a wider interest among the architects themselves, and a wider interest in the builders. We notice it in the developments in the United States, particularly in the New England States, in the great movement towards the improvement of public buildings, in the formation of guilds of civic art, and the education of public opinion. There is a return to the feeling that after all there is something more in life than mere living. There is the association of a higher aspiration and of the fitting clothing of the ideals, and the educative feature that comes along with them. Thus, I think, we are on the turn, and it seems to me we should emphasize it. I am very thankful to find that the architects are banding themselves together, and are working towards public standards, that they are beginning to criticize professionally certain structures that are put up, and to impress on governments and millionaires, and other people who have money to spend, that it is necessary, not merely to build, but to build well; and by the appropriateness of the setting to get the buildings to be, as I said, owned of nature. Take the bridges of Britain, those stone structures, and see how finely nature takes hold of them; clothes and adopts them, making them some of the most beautiful features in the landscape; also how impossible it is for her to take hold of certain structures, and how she holds back from them. There is a feeling which I would just like to touch on a little before I close. Why is it that the savage and the civilized man alike—anyone, indeed, who has a spark in him that responds to nature—recoils in horror from a burnt region? Is there anything so desolate as a wooded region swept by fire? Yet why is it that the burnt region should not be as attractive as the most fertile and green? Why is it that tumbled rocks, caused by earthquakes, will give us quite a picturesque feature? We say that the latter is beautiful, and picturesque, while the other is desolate and horrible. Why is it? It is that there is registered in our nature, as a result of our contact with outer nature through ages, the notion of what is normal and natural, as distinguished from what is abnormal and unnatural. When the fire-swept region is grown up again, when the fallen trees have been covered by the mosses—because fallen trees, merely as fallen trees, are not objectionable to the view, and especially when moss-grown—then it is attractive once more, because again owned of nature. Our interest in nature, therefore, and our feeling for it, should be the artistic test. It is, after all, the ultimate standard in beauty, in appropriateness, in form and all that. Why is it that one line is beautiful and another line not? There is no explanation in philosophy or mathematics for that but there is an explanation in the appropriateness of the curves to nature, whence man derived his appreciation. Therefore, I say nothing in architecture, whether in civic beauty, or in the development of domestic architecture through the country, will live or give satisfaction permanently, as some of the ancient structures do, except it be owned of nature; that is, in perfect harmony with these primary conditions.

But in making it harmonious with nature, it will not do simply to imitate the past. There is no use in our imitating the temple of the Greek, or the temple of the Egyptian or the Assyrian. Why? Because we have not their point of view; we have not their special aspirations, we have passed that stage long ago, and we might as well say that the cathedral-building Christians should have taken the Egyptian type, or that the Egyptians should have developed the Christian type. No. Both these things are perfectly splendid in their way, because they properly express the aspirations and feelings of the people at the time; and there is no architecture that will stand, it seems to me, that does not do that. We have, to-day, surely enough life and vigor and high aspiration to find their own appropriate clothing and setting so that they will, on the one hand, be the expression of civic and social interest, and on the other hand, be owned of nature. I know of no direction in which our wealthy men, our millionaires and so on, can more wisely spend their money, if they have to spend it on themselves, than in building fine mansions. That is what redeems Britain from being a very commonplace country in many ways, with a horrible climate nearly half the year, and yet great men putting their wealth into the stately, beautiful country houses, with their surrounding parks, have redeemed the country and educated the people. The mansion of the wealthy man is not merely for him; it may educate the people, it may raise their standards. It may ameliorate the ideas of life in a thousand ways, for all the community as well as for the owner; even as regards the interior of it, for there our English relatives set us an example, too, because they have freely opened their treasures and their interiors to the public; that is, to people who can appreciate them and derive benefit from them. And it seems to me that it is the duty as well as the privilege of our modern architects to direct the architectural movement in America, and to give us something that will be at once social and the embodiment of aspirations, and hence educative as well. And so it is proper that architecture should once more associate with itself in a perfectly normal and natural way all the other arts that were so long divorced from it; mural decoration, and statuary, and all these things shall come in once more and be harmoniously developed. (Applause).

DISCUSSION.

Mr. Symons: Mr. President and Gentlemen,—It was only from my desire to hear some discussion on Professor Shortt's able lecture that I could be prevailed upon to say a few words this afternoon. Prof. Shortt has taken us back to the time when art was an unconscious element, a mere protoplasm, a microbe. I do wish that there was something that could not be traced back to that blessed microbe; we are always face to face with these fearsome quantities, and now, if you please, our beloved calling has been traced back to such weird ancestory! Some of you may remember the words of Sir Joshua Reynolds—"the end of all art is to make an impression on the feelings and imaginations." There is no doubt that the first call upon architecture, its first duty, was simply to house the body; simply to form such a protection for the services of life, or as might provide for bare necessity. These requirements were met, and during the process other necessities became apparent, those which Prof. Shortt has mentioned namely the natural instinct for the beautiful, the true, the awful and the sublime; these had likewise to be satisfied; and it is in the development and satisfying of these nobler attributes of our nature that architecture finds its outlet. And as he said, as soon as a man has amassed wealth he endeavors to build himself a home that shall not only be the home of a wealthy man, but shall express his feelings and aspirations; and the means he has acquired enable him to satisfy his taste for what is beautiful and true. And the same thing may be said of a city. As soon as a city becomes prosperous the citizens endeavor to see how they can make it beautiful. We hear very little about beautifying our city, opening up squares, avenues or parks in hard times or in times of growth; but in prosperity, when we begin to feel that it can be afforded, we commence to look beyond the mere animal and gratify the desires of our higher nature. Have we not a perfect example of that growth without intense individualism, which Prof. Shortt so rightly upholds—and which was referred to by our President this morning when he said that we do not want the intensely individual in architecture—have we not that spirit beautifully shown in the history of Venice? In Mrs. Oliphant's book, "The Makers of Venice," she writes: "Where are her authors? Where are her sculptors? Where are her great men? Where are her poets? You cannot find them; you meet them nowhere. Instead of the man who made her what she is, we find everywhere the great Venice herself, the center of all their aspirations, the mistress of their affections; erasing themselves, thinking of nothing but her glory." It seems to me that what is so degrading in our own profession is the absurd endeavor to be intensely individual—individual in design, individual in attacking the great problems of the age, individual in every portion of our calling. How seldom it is that we call in the aid of a sculptor, of a decorator, or the aid of a landscape gardener when we are endeavoring to plan large schemes. No, we think so much of our individual power; we can do it all ourselves; and are we in consequence very far on in the life that Prof. Shortt has outlined to us? I am afraid we are not. We should aim to lose our individuality in the love of our profession, of our city and of our country. We have in our midst monuments that are grotesque in themselves and exemplify what I am speaking of; we have beautiful bits of sculpturing with badly designed bases; we have interiors designed without any relation whatever to intended decoration. I think the note that I would take from both Prof. Shortt's lecture and the remarks of our own President to-day, is this: To endeavor as architects and as a professional body to lose ourselves in the endeavor to benefit the city, the country, architecture and art. How can we best accomplish this? Sir Joshua Reynolds was looked upon as a great plodder, as a great worker, perhaps more than as a great aesthetic in his art, and he sums up the cause of all his greatness in his last lecture before the Institute in saying: "If we are determined to excel as individuals or collectively, men must go to their work whether willing or unwilling, morning, noon and night, and they will find it to be no play, but on the contrary, very hard labor." I know we have a problem ahead of us to benefit ourselves and others by this losing of ourselves, and it is not play, it is hard work. I have much pleasure, Mr. President, in moving a hearty vote of thanks

to Prof. Shortt for his lecture. Personally I feel that it has cut out much new ground, and I am only able to make a few remarks that will open discussion by people here who are more fully able to lead them than I. (Applause.)

The President: We shall be glad to hear not only from members of the Association, but from visitors who have come to hear Prof. Shortt. It is not really necessary to have a formal motion in order to express our thanks to Professor Shortt, but as we have one we must have a seconder. Will Mr. Price, of Philadelphia, second the motion?

Mr. Price: I do not like to take up any time, as I shall take up some later on, but I desire to say that I have been extremely impressed by Prof. Shortt's address, though it did not bring to me the same message that it brought to Mr. Symons. It seems to me that we have drifted towards the time when the development of the interest of the individual becomes the highest good for the individual and for the crowd as well; art itself will lose that microbe sting when we understand that it is our best means of individual development; that art does not mean, as Sir Joshua Reynolds said—I cannot quote the words—something to be looked at or something to give great pleasure essentially, but a means of expression; and by expression and through expression a means of creation, because if you come to analyze civilization—at least modern civilization—it will appear, I think, that the essential part is development by the individual and through the individual; and if you come to examine the means by which development comes you will find that there are very few; in fact, that they narrow down practically to one thing (as far as I have been able to analyze it), and that is to create new work. It seems to me the man who goes to college, or goes through any other course of preparation or study, gets development only; even there, as he takes those principles and remakes them for himself, as he becomes a constructive thinker; and my plea is for the greatest possible expression of self in our work, not only the expression of self, as the architect, but the expression of our co-laborers in architecture; because we are not the whole thing in architecture by any means. If architecture existed only on paper then we should be it; but architecture does not exist, as architecture, on paper, but in the concrete; and only as we can push along our own development—that does not mean a development that fights with everyone else's development, because if it is really the best sort it is an aid to everyone else's development and I would push our own development to its extreme—then we should become the best social architects and do the best social architectural work. And only as we help our co-laborers in the work of architecture to express themselves in their work can we hope to have the best results in architecture. (Applause.)

The President: The thing that struck me particularly in Professor Shortt's address is this unsolvable problem—now is it that the untutored savage is capable of creating art and the untutored hayseed is not? They seem to be in the same position. Architectural art after all is but the simplest expression of the pure emotion which the creator feels in what he is doing; if it is a house that he wants to create, his creation has the domestic feeling; if it is a fortress, he emphasizes (for very good reasons) the strength of the fortress; if he is an Egyptian and wants to create a temple, it naturally takes the form of the emotions which he feels in his religion, and a long interior, more and more thickly columned, ends at last in the mysterious chamber where resides his god; if he is a Greek his religion requires but a little statue chamber, and he decorates the exterior of the building for his own aesthetic gratification. When he becomes a Christian architect, we find his plan and the whole expression of the building (as exemplified by the Gothic cathedral) expresses exaltation—the uplifting of the Christian mind. Architecture, then, is merely the expression of an emotion which a man feels when he desires the building which he proceeds to erect or the work which he proceeds to make. How is it that the man is not nowadays able to feel these emotions truly? To me it is a problem without solution. Perhaps Professor Shortt can give one. But there is this that seems to come out of it: that the modern architect cannot do too much to cultivate his mind. It seems to be the cultivated mind only which is able to express the emotion which results in a work of art. We have lost the simple feeling; we are not in touch with nature as men used to be and we can only get back to it. I fancy, by further development, not merely by education—at least not merely by information; it is of no avail for a man to have architectural draughtsmanship at his fingers' ends if he has not a mind that can use it to good purpose. The question is one of capacity for ideas: he has got to be in a position to feel what architecture indicates. He can only do that by not so much informing his mind as by cultivating it; he has got to have the capacity for feeling the right emotion, and this seems to be only possible to a man of truly cultured mind. The direct lesson which I think we may have from it is that we need not be at all afraid of cultivating our minds, for the more we do so the better we are able to appreciate the simplest problem that is set before us. (Applause.) I have great pleasure in presenting to Prof. Shortt the thanks of the Association.

Prof. Shortt: In acknowledging the vote of thanks, it seems to me that there is after all an essential harmony in what has been said. That while this is certainly an age in which the social development is to be expressed in the individual, we have to work out our social aspirations through the cultivation and development of the individual: and it is certainly, as Mr. Price said, by the creative factor. He struck a very true note there, to my mind; it is only creation that is great. Imitation is only a preparation for creation; it is only a cultivation of ourselves; creation is the great thing, and the man who is educated—at college or anywhere—and does not get to the creative stage, is a failure no matter how beautifully he can imitate this, that or the other. And with reference to the point dropped by the President. Why is it that the hayseed has not got that which the primitive savage has? It seems to me that it is explained by much of the tendency of our life, of this utilitarian spirit, to get us out of touch with the natural conditions. There is no reason in the world surely why the log houses of Canada should not have been as artistic as the log houses of Switzerland, or of Russia, or of many other countries that represent a race not nearly so well

developed as the people who built those log houses in Canada. It is simply due to the fact that a great many of them had lost the appreciation for the occasion; they thought that in having to build their houses of logs they had something that was utterly impossible of decoration or art expression of any kind; hence the ordinary log cabin house of Canada gives no creative expression. It is a mere box to cover the person from the weather; whereas this very material in dozens of other countries gets a perfectly beautiful expression; and in simpler and humbler form, many of them, than our log houses. It is that feature that the President indicated, which we have to work against; and to get ourselves back to the point of view of a large realization of where we stand and how we are to express it. Thank you, gentlemen. (Applause.)

Mr. Price: I should like to offer one other explanation of why the farmer's house is different from the savage's house, and that is, the savage builds his own house and the farmer does not. The farmer hires one of us to do it for him; and, while it might express him, it does not. I think the proof of this is found in the fact that the farmer's outbuildings and his barns are generally better than his house; they are at least picturesque; and what is more, they are built appropriately, which his house is not. You will find the only real timbering work we do is done in our barns, and our farmers do it for us. It seems to me we might even yet go to the farmer.

THE IONIC VOLUTE.

Discussing this question at a meeting of the R. I. B. A., Dr. F. C. Penrose said the origin of the volute had been sought for in Assyria, Egypt, and elsewhere. He derived it from Greece itself, as the scheme he would explain enabled the exact figure of any true Greek example to be reproduced. In archaic Greek work, and particularly in the decorations of the Mycenean period, one constantly found the form of scroll in which every convolution of the spiral followed the first at equal intervals. This decorative scroll had no doubt been formed mechanically, as could easily be done by unwinding a string from a cylinder, forming a figure known as the involute of the circle. The question presented itself, How could a spiral having the character of the ammonite be produced? If the operator drew upon wood—or some other suitable material—the involute scroll, such as he had been accustomed to, and by shallow carving or otherwise raised the edges a little so as to form a helix and allow a string to be wound around those edges, and then unwound over a flat surface having a marker at the extremity of the string, he would produce the expanding spiral he was in search of. It did not give correctly the figure of the ammonite, but it had all the requisites of proportional expansion and perfect variation of curvature at every point, and coincided perfectly with Greek volutes.

The author gave two examples from Ephesus—the first from the archaic temple of Diana. In all later examples known to the author the two central convolutions of the spiral, or nearly so, were interrupted and concealed by the circle which formed the eye of the volute. In this case, however, the curve which would be evolved from the helix was allowed to extend from the central origin of the volute up to its junction with the abacus. By drawing a straight line through the central origin to the circumference on both sides, a calculation could be made to find a helix on the involute principle and this, when worked out, would be found to agree not only with given points on the circumference, but to correspond with the inner convolutions also and could therefore be extended to the whole of the volute. This correspondence clearly showed that the method of the involute spiral was that which was used by the architect employed by Crœsus. The volute of the later temple at Ephesus, the second example, had almost the same curvature, the only difference being in the surface moulding and the circular eye which occupied its centre. In the majority of the examples known to the author the eye of the volute was a separate piece from the main mass of the capital, and was formed by some kind of boss of marble or metal inserted into a circular hole prepared for it, centred very nearly on the place of the pivot of the helix, and always of sufficient diameter to receive it. Such an arrangement would have had obvious convenience for fixing the helix.

The volutes in all the examples in Asia Minor were probably described by means of helices similar to that mentioned above. But the Athenians demanded greater variety than that spiral so used could supply, and gave to their volutes additional expansion in the exterior convolution; still, however, working so by means of the involute form, but differently treated. This applies to the Propylæa, to the three orders of different size in the Erechtheum and to the temple of Nike. It was also used in the temple on the Hyssus, recorded by Stuart; and in the provincial temple at Bassæ. With the exception of this variation in the exterior convolution in Athenian structures, the same general scheme seems to have been employed in all true Greek examples, and the only liberty of choice given to the designers lay in the proportioning of the width of the volute to the upper diameter of the column and in that of the interval between the convolutions of the generating helix, in the size of the eye compared with that of the volute.—Architects' Magazine.

SOME SUGGESTIONS FOR YOUNG ARCHITECTS

Under this title Mr. A. A. Symon, President of the Dundee Institute of Architecture, Science and Art, in a recent inaugural address said that most lads who entered the profession did not do so for the purpose of making money. If anyone was foolish enough to harbor ideas of that sort he would not be very long in being disillusioned. Entry into an architect's office involved much hard work, but the prospect was not such as should discourage any young man. An apprentice's first duty was to keep his eyes open. He should be ever on the alert, and ready to improve his time, for deficient powers of observation always resulted in failure. They should never be afraid of displaying their ignorance. They were all learning, and it seemed to him so many things went to make up an architect's education that it would be impossible to acquire them all in a lifetime. He deprecated the present-day system of young men making football and recreation the business of existence. He advocated at this stage of an architects' career the closest attention to study, and counselled the younger members of the profession to avail themselves fully of the classes at their disposal. On completion of his apprenticeship an architect should seek employment in some other large centre, and there watch the methods of other people. When he suggested this course, however, he did not mean that they should remain away. There were as good opportunities at home as in other large centres. He advised every member to gain some practical knowledge of materials, as such would prove of great value in his professional life.

The London Lancet tells of a peculiar "disease" that has attacked the glass in the windows in York Cathedral. The glass is of the thirteenth and fourteenth centuries, and some pieces have become finely perforated and have lost their transparency. In fact they seem to have lost all the properties usually associated with glass. The Lancet also discusses the power of water and articles of food to dissolve glass and the prospects of consequent diseases.

INTERNATIONAL FIRE PREVENTION CONGRESS.

This Congress, convened by the British Fire Prevention Committee, is to be held in London, July 7th to 18th next.

The Congress will sit in General Congress and also in Sectional Congress. There will be six sections as follows:—I. Building Construction and Equipment; II. Electrical Safeguards and Protection from Lightning; III. Legislation and Adminstration; IV. Fire Survey and Fire Brigade Patrols; V. Insurance and Fire Losses; VI. Standards and Tests for Materials.

The primary objects of the Congress, among others are as follows:—

I. To discuss the practice of building construction and the application of building materials from a fire preventative point of view; to compare the practice in different countries, and to inquire into the latest materials and systems of construction available, as also the latest inventions for the general equipment of buildings.

II. To discuss the equipment of buildings particularly in relation to the application of electric power and electric light, and to receive the views of electrical engineers and fire brigade officers as to the origin and prevention of electrical fires, including fires caused by lightning.

III. To discuss the legislative enactments in force in cities and districts, particularly in respect to the limitations of area or cubical contents for warehouse buildings and workshops, and the means of separating and uniting such buildings, also the means of escape in case of fire; further, to consider particularly the regulations governing the construction and control of theatres and places of public resort, and the provision of staircases and means of escape for the audience and employees; as also the regulations governing the construction of dwelling-houses and houses let in tenements, and the amount of fire-resistance to be provided and the means of escape in case of fire.

IV. To discuss the best means of watching or inspecting buildings and plant exposed to fire risks without due inconvenience to owners and occupiers, the practice of fire brigades in this direction, and the experience of the various fire patrol systems.

V. To discuss the practice of insurance against fire; to ascertain the systems adopted in various countries; the risks insured against; the regulations and requirements of the national, municipal, public and private insurance corporations, and to inquire into the systems of mutual insurance, the precautions taken against incendiarism, the statistical record of fire losses, and the preparation of uniform fire maps and plans.

VI. To discuss the best means of recording the causes and effect of fires, and tabulating the results, so that a basis for comparison may be obtained and standards compiled for various degrees of fire resistance required in different buildings and suited for various materials; to discuss the best methods of testing materials and recording the facts of such tests for the information of those engaged in the construction, use and protection of buildings from fire.

The Parkin & Somerville, Elevator Co., whose announcement appears on front cover of this number have recently commenced the manufacture at Hamilton, Ont., of elevators for all purposes, and have successfully carried out a number of contracts in this line.

Mr. Edmund M. Wheelwright, the well-known architect of Boston, recently delivered an interesting lecture illustrated by lantern slides in the Art Gallery, Montreal, on "Bridges." The lecturer traced the history of bridge construction from the time of the Romans, and pleaded that greater attention should be paid here as in Europe to artistic effect in bridges.

The richly decorated west front of the cathedral at Exeter, England, is to be remodeled in the interests of safety, the seven centuries old wall having shown signs of collapse. As much of the statuary as possible will be retained in the remodeled wall, and the remainder will be carefully copied and restored. The famous cathedral was begun in 1280 and completed in 1371, the west front being finished last.

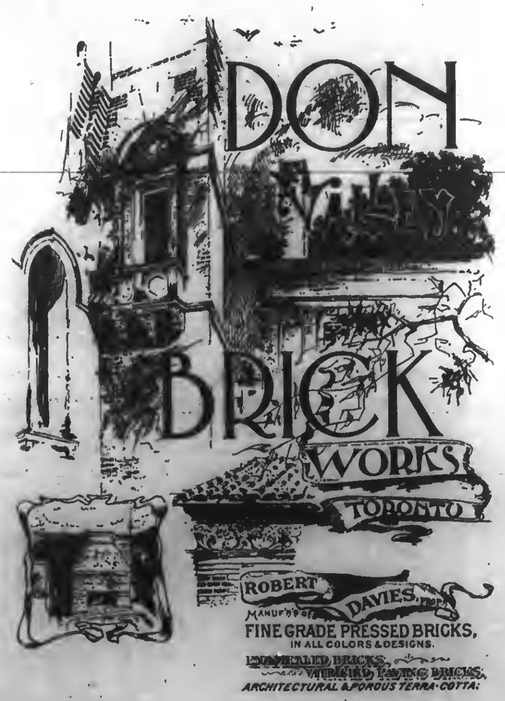
BUSINESS NOTE.

The Frink system of reflectors is the best for lighting pictures in galleries and private houses and is coming more and more into use. The Frink Company have recently completed the installation of their reflectors in the American Art Galleries New York, also in the new galleries of the Drexel Institute in Philadelphia and have just finished putting them in the delivery room of the Boston Library for the purpose of lighting Mr. Abbey's "Holy Grail" decorations.



THE DECORATION OF CEILINGS.

An authority upon the subject of interior decoration has expressed the opinion that if only one part of a room be decorated, that part should be the ceiling. He says:—"Nothing appears to me more strange than that our ceilings, which can be properly seen, are often white, while the walls, which are always in part hidden, and even the floor on which we tread, should have color and pattern applied to them; and of this I am certain, that, considered from a decorative point of view, our ordinary treatment is wrong."

A ceiling may be an object of great beauty, and it can be seen as a whole, therefore in many public buildings the decoration of the ceiling might be very advantageous.

If a ceiling be quite flat and without raised mouldings or ornaments, all decorations placed upon it must be flat also, and must not represent fictitious relief, for no shaded ornament can be satisfactory when placed as the decoration of a flat architectural surface.

Many circumstances tend to determine the nature of the decoration to be applied to a ceiling; thus, if a ceiling be structurally divided into square panels, the character of the ornament is thereby restricted, and should these panels be large it would probably be desirable that each be filled with similar ornamentation; while if they are small, three or four different patterns may be employed, if arranged in some orderly or regular manner.

On the Continent, and to some extent in this country, ceilings have been painted with large pictures, covering the whole or a portion of the surface; but this is quite a wrong method, for a picture of such a kind could only be seen the right way up, from one point in the room; from all others it would be viewed upside down, or from one side or corner.

But apart from this, a ceiling being flat surface, all decoration upon it should be flat also. In many of the French ceilings the picture is painted in such a position as to be seen properly only by a person standing with his back to the fire.

The Egyptians decorated their ceilings, so did the Greeks, the Byzantines, the Moors, and the peoples of the Middle Ages, and the ceilings were by no means always of a light colour. It is remarkable that so few of our public buildings contain rooms with well decorated ceilings, but there have been more executed during the last few years, and there appears to be a tendency for their adoption in connection with modern buildings.

Architects and building owners should be interested in the announcement on page i of this issue of the Smith-Warren Co., of New York. The company manufacture the "Smith" system of metal window frames and sashes for holding wired glass. These windows have proved to be an efficient protection against fire and are accepted by the Underwriters in lieu of fire shutters. All moveable sashes, whether sliding or swinging close automatically at 155 degrees of heat. The sliding sashes are also made for cleaning from inside of building. As a means of reducing the fire risk and thereby lowering cost of insurance these windows are worthy of consideration and trial.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingles stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

PERSONAL.

Mr. J. Greenfield, architect, has removed his offices to Room No. 24, Canada Block, Winnipeg.

Mr. Thos. Kennedy, after an absence of three years in the Northwest, has returned to Barrie, Ont., and resumed his architectural practice.

Mr. A. W. Peene, architect, has recently filled the position of superintendent of the Hamilton Art School, pending the appointment of a permanent superintendent.

Mr. Ebenezer North, a prominent contractor, and one of the oldest residents of London, Ont., died unexpectedly of heart disease in that city on the 14th inst. The deceased was born in Lincnolshire, Eng., seventy years ago.

Mr. A. J. Cooke, architect, of Montreal, died at his residence at St. Lambert, on Feb. 23rd, from hemorrhage of the lungs. Mr. Cooke was a Londoner by birth and was apprenticed there by Mr. Andrew T. Taylor, F.R.I.B.A., coming out to that gentlemen's Montreal office in 1883. For some six years he was with Mr. McLea Walbank and then started in practice for himself. He was well-known, especially in Westmount, where he built upwards of one hundred houses.

An artistically printed booklet referring to the manufacture and uses of Portland cement has been published by the Canadian Portland Cement Co., Limited. It contains numerous illustrations of works in which the company's material was employed.

Putting in Foundations in Winter.

For several years in Toronto there has been but a very short gap between one building season and another. In fact, if account is taken of the new structures on which inside work is in progress throughout the winter, there may be said to be no gap at all. The present winter, which has been a favorable one for architects and builders, witnessed the putting in of foundations for new buildings during January and the early part of February. The method adopted to prevent frost from getting in below the foundations is to cover the work when not in process of construction, with manure. It is admitted, however, that there is considerable risk attending the practice—the success of which largely depends on securing a week or ten days of favorable weather. We have been told of instances in which frost having got below the footings of a cellar pier, caused the architect trouble from settlement throughout the whole progress of the work.

Building Failures.

The Montreal papers have already recorded this year several instances in which buildings in that city have collapsed. Such cases have been altogether too frequent in Montreal during the last three or four years. In some instances, as in the case of a biscuit factory on Delorimer Avenue last month, the collapse came while the buildiag was in process of construction. In others, the buildings had been standing for years, and probably succumbed to strains imposed on them which they were never intended to bear. In the case of the uncompleted buildings the explanation is not so clear. Their collapse would seem to be due either to faulty materials or construction or to carelessness on the part of contractors in failing to properly support the unfinished walls. Whatever the cause, greater care should be exercised lest human life be sacrificed, which through good fortune rather than good management, has not yet occurred.

Slip-Shod Tendering.

An inspection of a batch of tenders, even for an ordinary house, will show the necessity for a better all-round education and in particular a better business training, for contractors. It is evident that many contractors do not study and grasp the meaning of the specifications on which their tenders are based. The specifications may in the most explicit manner require the contractor to state what deductions in price he will make if certain parts of the work are omitted, but as a rule he pays no attention whatever to the requirement and it is impossible for the architect to know whether his tender is designed to

include the whole work or not. Then there is the wide variation in tenders to which previous reference has been made. Tenders for the carpentry work of a house of moderate price are found to be as much as one thousand dollars apart, and even in so small an item as the electric wiring, there is a difference of fifty dollars between one offer and another. There would seem to be something radically wrong either with the methods or morals of contractors when such wide differences as these occur, and in view of such apparently hap-hazard figuring it is surprising that the percentage of failures among contractors is not greater than it is.

The Designing of Commercial Buildings.

The Confederation Life Building, Toronto, is serving as an example of the unsuitability of gothic design for commercial buildings. In order to secure an adequate revenue the owners were compelled two or three years ago to have remodelled the western front, to serve as banking premises. With the same end in view it is now proposed to redesign and reconstruct the upper part of the Yonge and Richmond street fronts as far back as the main tower and to add three stories to the height. When this is done the revenue from this part of the building will probably be more than double what could have been obtained before. The alterations will represent a large expenditure, the greater part of which might have been saved if the purpose of the building and its revenue producing value had received proper consideration by the designer and those responsible for the selection of this particular design from among a large number submitted by architects in competition. Architects, owners and judges in architectural competitions should alike be impressed by the lesson which the history of this building teaches—that a plan for a building is successful in so far as the requirements are properly considered and provided for. Following this in order of importance should come the effort to make the building pleasing in appearance, which with a skilled designer is always possible.

Dominion Exhibition.

Assisted by a grant of $50,000 from the Federal Government, it has been decided to hold a Dominion Exhibition in Toronto this year. For some time we have advocated this project, and are therefore gratified to learn that it has assumed definite form. The question arises however, whether four or five months is sufficient time for the preparations to be made on a sufficiently ample aud complete scale. It is stated that the Industrial Exhibition Association have already been at work on the enterprise for several months. If this is the case, no douht many of the arrangements are already well under way. Every patriotic Canadian should lend his assistance to make this Exhibition truly representative of the resources of the entire Dominion. The hearty co-operation of the local governments, commercial bodies and leading men of the various provinces forming the Confederation, is essential to success. The railway and steamboat companies can also greatly assist by granting such low transportation rates as will encourage visitors to attend from every part of the country. It is to be hoped that means will be found and steps taken to bring before the visitors to this Exhibition the improvements in design, materials and methods which have marked the progress of the building industry in this country, especially during the last decade.

An Important Decision

Consternation has been caused in the ranks of the labor unions in England by the recent decision of the Superior Courts, condemning the Amalgamated Society of Railway Servants to pay $115,000 to the Taff Vale Railway Co. as compensation for damage sustained by the company by reason of the intimidation of their employees by the Society during a strike. In this case, as in that of the journeymen plumbers in Toronto last year, the strikers did not hesitate when it suited their purpose to violate their agreement with their employers by quitting work without giving fourteen days notice as required by the terms of their engagement. The secretary of the Society has admitted that had the Society lived up to its agreement, the strike could not have succeeded, as the company would have been able to get the required help. When the company were granted an injunction preventing interference by the strikers with their workmen, the society capitulated. Then the company took the agressive and sued the society for $150,000 damages, and as stated, were awarded $115,000. The situation in England now is that men still have the right to organize, but they may not strike until they have given the legal notice, and when they have quit their employment they must not interfere with the men who take their places. If they do they are liable in damages, and as the present decision shows, substantial ones at that. An effort is now being made to have the law changed in such a way as to relieve the Unions of the responsibility placed on them by the courts.

Wired Glass.

The Chief Engineer of the New York Fire Department has recently expressed high appreciation of wired glass as an efficient protection from fire. The fire-resisting qualities of this material are now generally recognized. According to the American Architect, however, except when fire is present, it has undesirable, even dangerous qualities. This journal cites as proof the South Terminal Station in Boston. In the windows that face east, south, and west, and in the thousands of feet of pent-roof over the street sidewalks, there is said to be hardly a sheet of the glass that is not cracked and shivered into a dozen or a hundred different pieces of glass, just now held in place by the embedded wire and the unequal planes of fracture of the glass itself. But where cracks are, there moisture and acid-gases can penetrate, and when corrosion has done its work on the wire there is likely to be many a repetition, less innocent, too, of the incident which attended President Roosevelt's reception in Boston a few weeks ago, when a sizable piece of this shattered wire-glass fell onto the platform not far from the President. Meanwhile before the time comes when falls of heavy pieces may be looked for, much of this shattering of the glass is already accompanied by the flying of fine splinters of glass. As fracture occurs least often on the side, and most frequently where the windows face the rising sun, it is evident that the manufacturers must give further study to the qualities of radiant heat before wire-glass can be held to be a perfectly safe material to use.

TOM MOORE HOUSE AT STE. ANNE, NEAR MONTREAL.

HIGH BUILDING.

It is satisfactory for the rest of the world that New York should proceed as fast as it can to the logical extreme in high building. What the rest of the world wants to know is, what will it come to? What is the limit; and what are going to be the consequences of building up to the limit?

The limit in height is practically in sight. Passenger elevators, which were the generating factor in these buildings, are also fixing their limitations. Accessibility to the street level is what is required for an office; and, when buildings are so high that time is wasted in going and coming in the elevator, the offices in the highest floors will not rent sufficiently well. The device of express elevators gets over the difficulty to some extent, but in the first place there is a limit to the percentage of floor space that can be given up to the elevator shafts, if the building is to pay; and in the second place there is a speed limit in elevators. What is known as a "nausea limit" is recognized; anything above this rate of speed is found to be uncomfortable—at least for landsmen. For men this rate is said to be 720 feet a minute; for women not more than 600 feet; and the descent must be much less rapid than this. Anything faster than 400 feet a minute going down, is distressing; so that about 600 feet per minute up and 400 feet per minute down is the maximum for an express elevator. The floor to floor elevator is still further reduced in speed, to enable the operator to make a prompt stop. If, with higher speed he bobs up and down at every floor—a consequence partly of human weakness and partly of the elasticity of steel rope—there is no ultimate gain in speed and considerable waste of power. Limiting calculations are often upset by new inventions; but, where the human body is the measure, there is a standard which may be relied on not to change. It is difficult to conceive of more rapid motion up or down for human beings than the present nausea limit, or of more abrupt stops at this rate of speed without great discomfort to the occupants of the car; and we may therefore accept as a scientific datum the present opinion of engineers in New York, that the limit of business buildings due to the limited speed of elevators, is between twenty-five and thirty storeys.

This may be the limit of height, but how to fix the limit of continuity. A sky scraper at intervals is a gain in every way; it gives well lighted, airy, and quiet offices; and it makes the street picturesque. A row of sky scrapers converts the street into a box canyon of unwholesome gloom; but it is not to be compared to the gloom and unwholesomeness within the buildings themselves. This condition of affairs is rapidly approaching in New York. There is what almost amounts to a skyscraper war going on. The early tall buildings in which, with more confidence than judgment, the party walls were filled with windows, are now in an awkward position. Skyscrapers are rising beside skyscrapers and blocking up whole walls of windows. Rooms which, when the buildings were erected, had the winter sun and the summer breeze, are now sealed up in darkness forever; and the sanitary consequences are beginning to cause alarm. In the lower rooms, in a street of continuous sky-scrapers, there is no light anyway; and, if darkness is to invade the upper storeys too, the unwholesomeness of the overcrowding in these expensive offices is going to be as bad as that in the poor tenements, which so much effort has been made to stop. At a recent meeting of the Municipal Art Society, a prominent speaker said:

"I read in my newspaper to-day of the benevolent project to build a great hospital for consumptives, the victims of tuberculosis; where they may have air and sunlight. And in the same paper I read of plans for a thirty story building. What are we trying to do? What do we mean by putting up these horrible structures, to the lower floors of which no light can ever penetrate? . . . We build hospitals for the poor consumptive, and then we turn around and erect skyscraping structures where consumption may breed, so that we shall not lack for patients."

It is not merely the darkness, but the crowding of the streets and buildings which is a menace to health and safety. This same speaker calculates that "when Broadway is lined with these structures, there won't be room for the tenants, unless they are packed horizontally thirty feet thick." It is not hard to believe that this calculation, if checked, will be found to be not far from the truth. It was calculated at the beginning of the year that the buildings of nine storeys or more in the lower part of Manhattan Island, below Leonard street—that is to say only in the tall building district proper—have added the floor area above their fifth storeys, 180 acres of area to the island. The estimated cost of these buildings was $33,000,000. There is said to be $10,000,000 worth of buildings of the same sort in process of erection now, so that, as area may be presumed to compare consistently with price, when these are completed, which will not be long at the rate these buildings go up now, there will be added to this small district 240 acres of standing room above the streets; but there will be only the same old streets to walk in, and these more than ever filled with vehicles from other parts. The Broad Exchange Building has a floor area of 12½ acres and a normal population of 4,000 persons. Apply this rate of population to the 60 acres or so of floor area (above the fifth storey) which are now being constructed and it will appear that this portion of New York is about to receive an increase in daily population of at least 20,000 souls. If they only were souls; if, "in going from place to place," they need not "pass through the intermediate space," it would be all right; but 20,000 hustling bodies in streets where one has already, in going to keep an appointment, to allow time for hindered progress—it is nearing the limit.

The cure is exhibited in a trio of buildings on Broadway; a two-storey bank between two sky-scrapers. This is, at any rate, the solution of the light and air problem. It would also solve the problem in design. The two storeys of the bank run with the two storeys

which constitute the base of the tall building; the bank's cornice with the top member of this base; their columns and arcades are fairly comparable. Here is dignity without monotony, picturesqueness without extravagance, height without gloom; every gain without any loss except loss of space, and loss of space is gain in this case.

What other cities have to learn from New York is to put the limit out of the question by taking precautions in time. The limit is not practical. It is not worth while to shut numbers of people in darkness, for the sake of getting them all together, only to find that it would be better if there were not quite so many together. The limit of elevators, and the limit of traffic and transit in the streets, seem to point to the same moderation in close building which is indicated by the requirements of planning for light. It is no extreme to advocate the attainment of this moderation by municipal regulation, requiring that every tall building shall be isolated above such height as usually forms the base storeys of a sky-scraper. This allows for such an arrangement as is suggested by the bank on Broadway between two such buildings. It would make a satisfactory street effect if the cornice at this height were continuous and the sky line above broken at intervals, more or less regular, by buildings more or less tall.

A way to bring this about would be to require every high builder to isolate his upper storeys by the purchase of land sufficient for the purpose. This would not be tyrannical legislation. If any criticism is to be made of it, it might be called grandmotherly legislation; for it is looking after the interests of the high builder himself to compel him to guard the value of his building in this way. It is not however entirely grandmotherly, for the interests of the public are also guarded in matters for which it is certainly within the province of the City Fathers to care, viz., light and air and reasonable density of population. There is also plenty of precedent, in cities which owe part of their success to regulations of this kind, for requiring that the low part of the building shall have for æsthetic considerations, a cornice line of a fixed height.

W. A. LANGTON.

DECORATIVE PANEL FOR A DINING ROOM—G. A. REID, R. C. A.

Messrs. King and Bannigan, of Boston, are reported to have purchased a large plaster quarry at Hillsboro, Albert county, N.B., and to be making arrangements to open up the work and to prosecute it in a vigorous manner.

The Lake Manitoba Quarry and Transportation Co. has been formed to develop extensive deposits of excellent building stone at the Lake Manitoba Narrows.

BY THE WAY.

There are said to be within the limits of the city of New York two hundred thousand inner rooms unprovided with means of ventilation. To this cause is largely attributed the increase in the number of consumptives.

× × ×

The inconvenience arising from lack of uniformity in size of bricks is evidently not confined to Canada. A petition has been presented to the legislature of Massachusetts praying that the standard for face bricks shall be fixed at 8⅜ by 4¼ by 2¼ inches and for common brick at 8¼ by 4 by 2¼ inches.

× × ×

Recent excavations in the far east have revealed the fact that the Jerry builder had to be reckoned with one thousand years before the time of Moses. The following has been found among other enactments of a Babylonian ruler of that period:—"If a builder build a house and finish it, but does not make it solid, and if then the house fall and kill the owner, that builder shall be put to death. If it strikes the owner's son dead, then the son of the builder shall be put to death".

× × ×

The Deputy Chairman of the Liverpool Corporation Housing Committee thinks he has solved the problem of the cheap and substantial construction of dwellings for the dispossessed slum population. He proposes to use very large slabs of concrete made from refuse-destructor and clinker cement, hoisted into position and bolted together. A quicker and therefore cheaper method than this would be the plan attributed to Thomas A. Edison of pouring the concrete into a mould of the desired form.

GLASS-FACED BRICK.

The Cleveland Leader says that a new company has been organized lately to manufacture glass-faced brick. A number of prominent Cleveland men are financially interested in the project and the concern is looking for a factory site of from three to five acres.

The new brick is another of the great variety of concrete building material now being manufactured. A glass plate is laid in the bottom of a mold, and the concrete mixture is poured in on top of the glass. The concrete hardens on the glass, thus forming a brick or building block with a very brilliant exterior.

This kind of brick is for use in such places as courts and light wells in large buildings, where the glass becomes a reflector, and on account of its smooth surface does not become soiled easily, and is readily washed. The new process will yield a product similar to enamel brick.

INTERCOMMUNICATION.

Communications sent to this department must be addressed to the editor with the name and address of the sender attached not necessarily for publication. The editor does not hold himself responsible for the expressions or opinions of correspondents, but will, nevertheless, endeavor to secure correct replies to queries sent in. We do not guarantee answers to all queries, neither do we undertake to answer questions in issue following their appearance.]

"Manitoba," Winnipeg writes: In your issue for this month "City Builder" complains of smells from the drain. I think he will find this comes from the inlet to the so called fresh air pipe outside, and does not necessarily mean any defect in the plumbing work. Let him put his nose in the fresh air inlet whilst some one lets off a charge of the water closet and I think he will find an outrush of the offensive gas complained of which would show the house drains to be foul. Let him then put a teaspoonful of "Permanganate Potash" crystals into the closet tank, flush down same once or twice and in about half an hour test the fresh air inlet again, when he will find the outrushed air to be sweet. The Permanganate Potash should be applied occasionally and I know that this has remedied several bad cases. Stinking gas forced out of fresh air inlet will blow into the house when windows are open. The Permanganate Potash has been bought here as low as 35 cents per lb. so that the annual cost for house for its use should not be very great.

From "Young Carpenter"—I am going out to settle in New Ontario, and expect to have several frame barns to build, and would like to know of the latest improved methods of framing timber barns. A sketch of an end "bent" would help me very much, giving size of timbers, pitch of roof, and such other details as may be useful?

ANS.:—The elevation of timber barn shown in Fig. 1, is about as good an example of frame barn building as we know of. This plan is useful where it is desired to have the lower floor or ground all clear, for example, for a wagon-house. The plan also serves quite as well as under other circumstances. The frame makes a

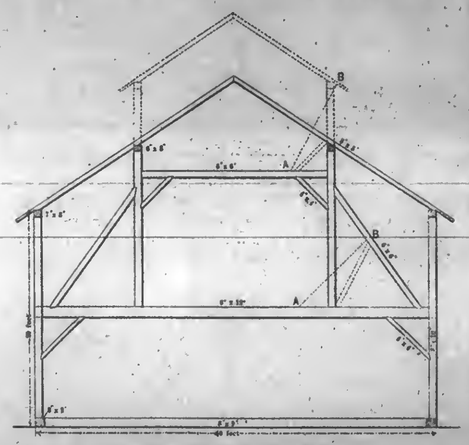

FIG. 1.—END OF A TIMBER BARN.

very rigid structure. The purlin post should be centered, tennoned, dovetailed and keyed into the beam, also drawbored. The beam should also have dovetailed tennons ke ed into the post with drawbores, the frame without guards or guards either 3 or 4 inches in from the base of the post, according as you use either 3 or 4 inch studs. These extend from the sill plate and are nailed or spiked to the guards. To support the floor timbers or joists spike a 2x4 piece on the sides of the beam and let the ends of joists rest on these. Mortise or dovetail one or two of the joists in each tier for ties, cover with good siding. If it is desired to use a hay-fork and the purlin beam is in the way we would suggest the plan of framing as indicated by the dotted lines. A B indicates a rod with no strain. A guard should then be framed into the purlin post, where the plate is now, for top end of lower tier of rafters. This plan gives an excellent method of ventilation, and, is better in both utility and appearance than the usual gambrel roof.

A A and B B show the lines of braces if such are deemed necessary. The barn is 40 feet wide over all. Sizes of timbers are shown on the sketch.

From "Amateur Decorator"—Will you kindly inform me as to the kind of "gum" or "shellac" that is used by plasterers for preventing suction in plaster work, and how is the material dissolved?

ANS.:—Use ordinary shellac which may be obtained from any druggist. The most suitable solvent for shellac is methylated spirit. Place 1½ lb. of orange shellac in a stone bottle with 1 gal. of methylated spirit and agitate at intervals until the shellac is thoroughly dissolved, after which the preparation is ready for use, and must be stored in an air-tight vessel; apply quickly with a fine-hair brush. The cheapest shellac is a deep orange color, and it will color your plaster. If this is an objection get white shellac, and dissolve and apply in the same way as for the orange.

From "Contractor"—I have just completed a home for myself, in the suburbs of the town I live in, and I want to finish up one little corner in my sitting room, with a lounge seat, reading desk and book case, making the whole into a sort of bachelor's cosy-corner. It must be made in one corner of the room in which there are no objections. Can you publish some sort of a design suitable to what I require; if so I will appreciate it very much?

ANS.:—In answer to this request we publish the illustration shown in Fig. 2, as being near about what is asked for, so far as we can understand it. It will be seen that this "nook" is formed by having a book-rack at one end, the side of the room forming the other end where a plain reading shelf forms the boundary. The reading shelf is placed near a window so that ample light is given. If there is no window in this position then the order of the scheme may be reversed to suit conditions. The back of the "nook" may be papered as shown, with a narrow moulding dividing the paper from the other part of the wall, or it may be upholstered, or even panelled, according to taste. The book-rack and reading shelf are simple affairs but may be elaborated if desired. A three-leafed screen may be placed in front of the opening if more seculsion is desired, and the little stand removed altogether. Properly managed this "nook" may be made quite attractive and add very much to the appearance of the room.

From "Ambitious Workman"—I am a young man have learned my trade as a carpenter, and have a general knowledge of brick and stone work, and of painting and plastering, but feel that this is not enough to enable me to become a successful building contractor, which I desire to be. What kind of education should a builder and contractor receive? In addition to a good knowledge of building construction, is a knowledge of estimating and taking out quantities an absolute necessity? Any information or "pointers" will be thankfully received.

ANS.:—Something more than a fair knowledge of building construction is required. A builder and contractor should know all about every material that is used in building, such, for example, as the place or origin, the best place to buy, the best method of using and the faults that have to be allowed for or provided against; and he should be continually on the lookout for new materials, or for new methods of using existing materials. He should also be conversant with all rules

of arithmetic, with algebra up to simple quadratic equations, and geometry, and be able to calculate many things mentally. Land surveying is desirable so that buildings may be set out with facility, and quantity surveying is an absolute necessity. These two subjects can either be acquired under a private tutor, or at any technical school like the one in Toronto. A practical knowledge of estimating is also absolutely necessary, but this can only be acquired by learning the actual cost of materials and the actual cost of the labor that is required in order to use these materials in a building. You should take a fair supply of building journals in order to keep in touch with current building events and improvements, and should stock your library with a good assortment of standard works on building matters, and above all keep a copy of the "Canadian Contractor's Hand-Book and Estimator" on your desk for daily reference. This work, along with Hodgson's "Estimating Brick and Frame Buildings," will give you an insight as to the proper methods of taking out quantities, and making estimates for all kinds of buildings. Experience alone, however, will be necessary in rounding off your fitness to become a successful contractor.

FIG. 2.—A COSEY READING NOOK.

From "Builder"—I have a segment to lay out, the chord of which is 28 feet, and the rise 3 feet; how can I get the curve without going to a great deal of trouble?

ANS.:—There is no royal way to solving questions of this kind; more or less knowledge of mathematics and geometry in particular is required in matters of this sort. However, here is a method that is about as simple and reliable as can be, and is employed, we believe, in ship building establishments for getting curves in many instances. Lay off the baseline AB, Fig. 3, for instance, 28 feet. At center, C, erect the perpendicular CD, representing the height or spring which, for example, in this case we make 3 feet. From G as center, with CD as radius, describe the arc DE, which divide into three equal parts. Also divide the space GE into three equal parts. Then draw lines cutting the points thus established, as shown in the sketch by 1 2 and 3 4. Divide each half of the baseline AB into three equal parts. Set the bevel to the angles 1 2 C and 3 4 C, and apply as shown at 5 6 C and 7 8 C. Repeat the same operation in the other half of the base. Draw lines 5 6 and 7 8, on which set off respectively the distances 1 2 and 3 4, as shown. Repeat this operation in the opposite half of the figure, then a thin piece of wood, sprung from A to B in such a manner as to touch the points just determined, will give the line of the arch.

From "Contractor"—I have taken a contract to build a stable in which the horses are to be stationed on the second floor, and I would like a little information regarding the concrete or cement floor which I have to put down under the horses feet. Will you kindly give me a few hints on the subject?

ANS.:—The floor, should, of course, be one slab of cement with the necessary gutters worked in to carry away the water. It should have iron ribs embedded in the correct position to give the greatest tensile strength to the slab, but being completely encased on every side by the concrete of the floors. The thickness of the floor and the weight and section of the iron ribs would be determined by the span, but the quantity, and therefore cost, of the iron would be very much less than the usual quantity and cost of the ordinary and bad system of heavy iron girders, which cut into pieces

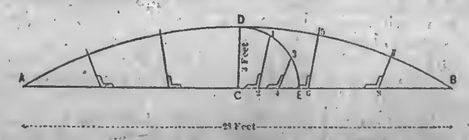

FIG. 3.—SHOWING HOW TO DIVIDE A LARGE SEGMENT OF A CIRCLE.

and reduce the strength of the concrete, and leave iron flanges exposed to the action of rust and fire. The concrete floor, with iron ribs, will be strongest, most fireproof, and dampproof, will have no lateral thrust to be counteracted, as in the case of brick arches and girders, and will also be cheaper. The surface can be finished with a coat of asphalte, paving bricks set in cement or smooth cement. We know of cement stable floors that have resisted the wear of heavy horses for over 15 years without repairs or injury. It is important that the work should be executed by persons thoroughly conversant with the method of construction, and experienced in the selection, treatment, and manipulation of the materials, particularly the cement.

TOWERS IN THE GROUNDS OF MONTREAL COLLEGE, SHERBROOKE STREET, PROBABLY THE OLDEST STRUCTURES IN MONTREAL, DATING BACK SOME 250 YEARS.

METHODS OF CONSTRUCTION IN RELATION TO INSURANCE.*

BY JOHN B. LAIDLAW.

The construction of buildings has ever been, and doubtless will ever be, a very important matter to the companies insuring property against loss by fire, and it affords me much pleasure to spend a few moments with the Architects' Association in discussing the standard of building construction adopted by the C.F.U.A. It is possible that in the past there has not been sufficient co-operation between those who supervise the construction of buildings and those who fix the insurance rate based upon the details of such construction, but whatever may have been the policy of the underwriters in the past, there is no question that to-day they stand ready to welcome any improvement in building construction and to assist that movement by means of discriminating rates as between buildings constructed according to their standard, and those in disregard of them.

The Underwriters have always recognized some of the essential features of good construction, such as that the walls of the building should be of brick or stone; that roofs should be of incombustible material—but they have only to a limited extent given attention to the interior construction, except as regards buildings to be used as manufactories. For the latter there has been for years a fairly strict standard, which while not requiring a building to be of what is now called mill construction, demanded strong bearing walls; limited the height and the area of the building; imposed serious extras in rate if there was a mansard roof; also required elevators to be in brick shafts outside a building, or be properly trapped at each floor; required stairways to be enclosed and have self-closing doors at each floor; also called for double floors and of sufficient thickness to carry the machinery in the building.

In accordance with this standard there was to be no inside sheathing of walls. The ceilings and joists were to be left open, and, speaking generally, an effort was made to avoid any concealed spaces in which dirt could accumulate, and fire not only originate, but be difficult to locate and extinguish.

The standard required the heating and the lighting to be as non-hazardous as possible; also the boilers for generating steam were to be in an outside separate building.

These were the general requirements, in addition to which there were other special requirements for each individual class of manufactory, such as requiring dry rooms in laundries to be of safe construction; shaving vaults and dry kilns in connection with woodworking risks to be outside the building; painting and varnishing and upholstering in furniture factories to be in a separate section, and so on throughout the different classes of manufacturing risks.

These requirements have had a marked effect during the last few years in alterations made to old factories and in the erection of new buildings. It is now intended to adopt a stricter standard for manufacturing risks in accordance with the most up to date requirements of what is called mill construction, the main difference between the new and the old being that under the new the floors are to be without joists and made of solid planking laid on edge, resting on wooden beams supported on strong wooden posts, with 10 foot bays, as a standard; this solid plank floor to be covered by a wearing floor of at least one inch in thickness. Such a floor interposes several inches of solid timber between the stories of a factory and leaves on the under side an almost absolutely smooth surface in which, or upon which a fire has difficulty to secure a lodgment. If these floors are left absolutely intact, a fire can, with comparative ease, be confined to the floor in which it originates, and such is the purpose of mill construction, but it is well to bear in mind that everything depends upon that "if"—if the floors are left absolutely intact. I have in mind a factory not 50 miles from Toronto of such construction, where the floor was cut to bring up a stairway. They might just about as well have saved their money and put in an ordinary floor for all the benefit gained.

Tonight however, it is proposed to ask your attention to the possibly more difficult subject of the construction of buildings intended for ordinary mercantile purposes in cities and towns.

When building a factory the first consideration is the business or purpose to which it is to be put. There is usually plenty of ground. The factory can be of any size, or height, or shape that the business requires, and the question of external appearance is but a minor one; when however one comes to consider the construction of a building for mercantile purposes in the heart of a city, say on King, or Yonge, or Queen streets in the centre of Toronto, there are a number of matters which cannot be overlooked, and it is well if any safeguards whatever against fire are introduced. The shape of the lot, the question of light, the business to be carried on, the question of access to the upper floors, must all be considered, and frequently the architect is forced to design a sort of general utility building when the tenant may not have been secured before the work commenced. These conditions have been recognized by the insurance companies and a standard has not been imposed which is too hard, but if anything rather lenient. It does not in any sense call for a fire-proof building, but rather for a well constructed building of joist construction with lath and plaster finish. In such however, there are many hazardous features which the architect can prevent being introduced, which if placed in the building will either induce a fire, or assist to spread it, and so must be charged for by the insurance companies. The standard reads as follows:—

CANADIAN FIRE UNDERWRITERS' ASSOCIATION.

MERCANTILE SCHEDULES.

BUILDING STANDARD.

A standard building is one having walls of brick or stone (brick preferred), not less than twelve inches thick at top storey (16 inches if stone), extending through and 36 inches above roof in parapet and coped, and increasing four inches in thickness for each storey below to the ground—the increased thickness of each storey to be utliized for beam ledges. Ground floor area not over 2,500 square feet (say 25 by 100); height not over three stories, or 40 feet; floors of 2 inch plank, (three inches better) covered by ⅞ or one-inch flooring, crossing diagonally, with waterproof paper or approved fire resisting material between (if tin or sheet iron between, see deductions); wooden beams, girders, and wooden storey posts or pillars twelve inches thick, or protected

* Paper read before the Toronto Chapter of the Ontario Association of Architects.

iron columns; elevators, stairways, etc., cut off by brick walls or by plaster on metallic studs and lathing; communications at each floor protected with approved tin-covered doors and fire-proof sills; windows and doors on exposed sides protected by approved tin-covered doors and shutters, or wired glass in metallic frame or a water curtain; walls of flues not less than eight inches in thickness to be lined with fire-brick, well burned clay or cast-iron, and throat capacity not less than 96 square inches if steam boilers are used; all floor timbers to be trimmed at least four inches from outside of flue; heated by hot water or steam; lighted by gas; cornices of incombustible materials; roof of slate, metal, or tile; if partitions are hollow or walls are furred off there must be fire-stops at each floor.

For differences from above the following charges and deductions are made to and from the Key Rate of a town which is determined by the Fire Protection Appliances provided:

WALLS.

INDEPENDENT—Charge for each 4 inches deficiency in average from standard (if building over 4 stories high, double the charge)...	.01
On buildings over 3 stories high if average thickness less than 12 inches, add not less than.....	.05

If two independent walls adjoin, 4 inches may be deducted from average of these requirements. Charge for one wall only—the most deficient.

A standard independent wall should be 12 inches the top story and increase 4 inches for each story to the bottom. This would require if 3 stories, an average of 16 inches; 4 stories, 18 inches; 5 stories, 20 inches; 6 stories, 22 inches; 7 stories, 24 inches.

PARTY—Charge for each inch deficiency in average from standard (if building over four stories high, double the charge).....	.01
If party wall less than 12 inches thick in any portion, add not less than.....	.05

A standard party wall should be 16 inches at the top storey, increasing 4 inches for each storey below. Average required for three storey building, 20 inches; 4 storey, 22 inches; 5 storey, 24 inches; 6 storey, 26 inches; 7 storey, 28 inches, etc.

PARAPET.

Walls not Parapet, each exposed side.....	.01
Parapet walls exceeding one foot above roof on all exposed sides, deduct for each foot in excess of one (not exceeding a total of .03).....	.01
Poor bricks or poor quality mortar.....	.10
Glass and wood or iron fronts, for each not backed up with bricks and mortar.....	.03
Glass and wood for each backed up.....	.01
" " for each adjoining in row, in addition to above.....	.01
HEIGHT—For fourth story, add.....	.05
Fifth story.....	.10
Sixth story.....	.25
For each story over six, add.....	.40

These charges cumulative; for example a six story building would have 40 cents added.

If any story double height, charge for two.

HEIGHT—Two story building, deduct.....	.02
One story building, deduct.....	.05

STREET.

If street on which building fronts is inaccessible, unpaved, etc., not less than.....	.10

(No charge if no fire department, and no charge for side or rear streets).

If less than 60 feet wide, but over 50.....	.01
If under 50 feet add for each 5 feet less	.01

STREET WIRES.

If to interfere with fire department.....01 to	.03

WOODEN CORNICES, CUPOLAS, Dormer Windows or Verandahs.....

Not less than.....	.01

CEILING OR SHEATHING.

Wood (natural or painted) or Strawboard Ceiling, 1 story, .03; each additional story charge.....	.02
Wood or strawboard siding, 1 story, .03; each additional story charge.....	.02

Double each charge if wood be varnished.

If side walls furred and plastered, half charge for wood sheathing.

Cloth or paper ceiling or siding on wooden studs, each story charge.....	.10
Metallic studs and lathing throughout, deduct	.05
Metallic lathing on wooden studs, deduct...	.02

FLOORS.

Tin or sheet-iron between floors, deduct.....	.02
Water-proof paper or cement between floors, deduct.....	.01
Floors water-proof and also inclined with scuppers to carry off surplus water to sewer, deduct.....	.02
If floors exceed two inches in thickness, deduct .01 for each excess inch (in addition to above).....	.01
If grade floor fire-proof.....	.10
Each fire-proof floor above grade (not exceeding a total of 25c.).....	.05
No cellar or basement, deduct.....	.05

AREA (GROUND FLOOR).

2,500 to 5,000, sq. ft. charge for each 1,000 in excess of 2,500 sq. ft.....	.01
5,000 to 10,000, sq. ft. 3 stories, 1,000 in excess of 2,500 sq. ft.....	.02
5,000 to 10,000, sq. ft., over 3 stories, 1,000 in excess of 2,500 sq. ft.....	.03
10,000 sq. ft. or more, 3 stories, 1,000 in excess of 2,500 sq. ft.....	.02½
10,000 sq. feet or more, over 3 stories, not over 6, in excess of 2,500 sq. ft.....	.04

(Not exceeding a total of 200 cents).

10,000 sq. ft. and over 6 stories, double the area charge.

(Not exceeding a total of 300 cents).

If building is of standard fire resisting construction throughout, halve the area charge.

On-estory building, one-half the charge for 3 story.

Two-story building, two-thirds the charge for 3 story.

If curtain, cross or division walls, sub-dividing and strengthening the building, even though with arched openings, deduct 10% of area charge for each wall so dividing the risk, not exceeding a total deduction of 40% of the area charge. Communications with adjoining buildings unprotected, charge for area both buildings, and rate as one (allowing for division wall). If fire-doors on communications are not standard, rate as if standard and make an additional charge under "Exposures" for defective doors.

Single Occupancy—If only one tenant outside of dwelling and office tenants twenty per cent. (20%) of the area charge may be deducted.

Small Risks under 1,500 sq. ft. ground floor area and not over 3 stories high, deduct.	.05
FRAME REARS—Extensions for each 100 feet wall area, (not more in all than 15c.) charge..	.01

If brick veneered, metal clad, or with openings protected with approved metal covering half charge.

STAIRWAYS.

Enclosed in lath and plaster hallway or provided with automatic trap-doors in floors.	.03
Similiar to above with traps closed only at night.....	.05
Fire-proof enclosure, but defective doors, etc.	.02
Enclosed in wood.....	.07
Enclosed in wood with self-closing doors each floor.....	.05
Open.....	.10

If more than one stairway, charge for worst and add one fourth charge for each additional.

One half charge for stairway if charge for elevator—halve the smaller charge.

If elevator and stairway are contained in the same shaft or opening, only one charge for the two.

No charge for stairways in buildings occupied exclusively for offices and dwellings above first story when stairway does not open into store.

ELEVATORS.

Enclosed in lath and plaster shaft or hallway, or if provided with approved automatic trap doors at floors..... .05
Fire-proof shaft, but defective doors, or walls not through roof..... .03
Open..... .10
Wooden shaft without approved automatic traps..... .15

One-half above charges for elevators in buildings otherwise standard, or in office building.

If more than one elevator, charge for worst and add one-fourth charge for each additional.

WELL HOLES.

If open, add for each (half charge for approved traps) from..... .03 .05

CHUTES, VENTS AND DUMB WAITERS.

(Unless fire-proof shaft), and small floor openings—Add for each, (if trapped half charge)..... .01

SKYLIGHTS.

If of thin glass (less than ¼ inch), in any kind of frame, charge for first 25 feet of total area .02, and for each additional 25 feet of area .0½. If more than one small sky-light charge for each (not more in all than 25c.)..... .02

If skylight is monitor style, charge for square feet in sides as well as top.

If ¼ inch glass in wooden frames, half charge.

If ¼ inch glass in metal or protected frames, one-fourth charge.

If protected above and below by wire netting, halve the charge.

If wired glass in metal or protected frames, free.

Same charges for floor-lights less than ¾ inch thick.

IRON COLUMNS UNPROTECTED.

Cast Iron .03; steel or wrought..... .05

LIGHTING.

Electricity, approved..... .02

Any other system for lighting must be subject to approval of Local Board of Underwriters and charged for by rule.

Kerosene (no charge if charged for electricity), not less than..... .02
Kerosene lighting in hazardous risks, such as paint shops or carpenter shops, not less than..... .10

HEATING.

If by hot air furnace, not less than..... .03
Furnace with metallic cold air box, and all vertical hot air pipes, through brick walls and one register fastened open, add..... .02
Stove (for each additional stove .01). (Must have metal under)..... .02
Stove in wood working establishments... .05 .25
Natural gas or oil fuel, approved pressure regulating appliances..... .05

CHIMNEYS.

Not built from ground, but on brackets, charge for each..... .05
If inadequate for service required, or walls of flues less than 8 inches thick, unless lined with pipe, not less than..... .05
If resting on attic floor beams or roof joists, add..... .25
Poor bricks or mortar..... .20
Terra-cotta or cement..... .50

STEAM BOILERS.

(Other than heating). Charge if in basement .05; above basement .10; wood shavings for fuel 1.00 additional.....

If boiler in fire-proof room cut off in approved manner, no charge.

POWER.

Charge according to hazard.....

ROOF.

Composition and gravel, if not well covered. .02
Shingles (if laid in mortar 5c.)..... .10
Mansard with wooden frame, 4 story or lower building, for each lineal five feet, but not more than 10c. for one side or 15c. in all..... .01
Mansard on building 5 stories or more in height, ¼c. additional for each lineal five feet, for each story over four.....

BLIND ATTIC, ROOF SPACE, COCK LOFT.

Take maximum height if slanting roof, and charge for each vertical foot .01, not less than .03 or more than..... .05

AGE OF BUILDING.

Over twenty years charge..... .02

OCCUPANCY. .....

.....

.....

.....

Each ordinary mercantile occupancy in excess of one, exclusive of office and dwelling tenants, charge..... .02
Each hazardous mercantile occupancy, charge .03
Each light manufacturing occupancy, not less than..... .05
Occupancy exclusively dwelling above grade floor, if one family, deduct..... .10
(If only one floor so occupied, deduct .05)
Occupancy exclusively dwelling above grade floor if two families, deduct..... .05
Occupancy if more than two families, deduct Nil.
" if tenement house above grade floor, deduct..... Nil.
Occupancy if building occupied throughout exclusively for offices or dwelling and offices..... .15
Occupancy if occupied exclusively above grade floor for offices, or offices and dwelling..... .05

PROTECTION.

Charge if not within 300 feet of hydrant on 4 in. main circulating or 6 in. main dead end..... .05
Iron fire escapes outside of building, with landings at each floor, deduct..... .02
Casks of water or filled pails on each floor (6 filled pails to each 2,500 square feet of floor area), deduct..... .05
(One-half number may be filled with sand. One cask may be considered the equivalent of three pails.)
Standpipe, internal with tank supply, deduct .02
" " without tank supply, deduct..... .01
Standpipe, external, with siamese connection for use of fire department, deduct... .01
Each side or rear accessible to fire department (no deduction for front), deduct... .02
Fire department house, engine, hose or hook and ladder, within 300 feet .01; if next door or on opposite side of street deduct .02
Basement and sub-cellar perforated pipe sprinklers, deduct..... .02
Automatic sprinklers in basement, (no deduction if allowance has been made for sprinklers throughout building)..... .05
Roof hydrants if protected from freezing... .02
Floor beams and girders self-releasing.... .01

Auxiliary private fire plant, force pump, etc. .05
Watchman, with portable clock..... .05
" with electric detector..... .10

EXPOSURES. To be charged by inspectors according to circumstances.

CONFLAGRATION HAZARD. Charge for such when conditions require.

ADD FOR FAULTS OF MANAGEMENT, EASILY CORRECTED.

140 If stovepipes through floors or partition, not protected, .50; through window, roof or wall, with double metal chimney, .50; not protected, 1.00; entering bottom of flue vertically, .25; entering flue in attic or unused room, etc..... .25
140a Floor beneath stove not protected.... .05
141 Bottom of elevator shaft used for closets, etc., or waste..... .50
142 Swinging gas brackets or bracket lamps unprotected, for one .05. each additional one..... .01
143 Untidiness, rubbish, ashes, etc., especially in cellar or attic, .25; packing material not in bins..... .15
144 Cracked or bulged walls, thin and worn floors, broken plastering, broken windows, etc.....10 to .25
145 Empty boxes, rubbish, etc., in rear yard, alleys, window recesses, under sidewalk, gratings, etc..... .10
146 Open lights in show windows or electric bulbs covered with tissue paper or paper shades..... .25
147 Sawdust on floors, sawdust spitoons, etc. .25
148 Kerosene used to sprinkle floors..... .25
149 Ash and waste cans, not metal..... .10
150 Furnace top within 4 inches of wooden beams or ceilings, if brick; or within 12 inches if portable, with metallic shield .10 to .25
151 Fire-places, hearths on wooden beams, or floors within 16 inches of fire-place; or wooden fire-boards, or summer pieces, or unprotected wooden mantels, or open stovepipe holes.....05 to .25
152 Steampipes in contact with wood, not less than..... .01
153 Elevator or other shafts communicating with roof space..... .25
154 Electric lighting or other system, with installation not in compliance with underwriters' rules; or arc lights unprotected by tight globes or metal screens..... .25
154a Crowded merchandise without proper aisles, opposite or too near windows, overloading, not less than..... .25

Now if you will allow me I will take up each feature in detail.

First—the walls. It is necessay to have a solid wall, not only to sustain whatever weight the building may, during changes of occupancy, be called upon to bear, but also to stand firm and keep out a fire which may burn the neighboring premises. We therefore ask that the side walls shall rise above the roof three feet, as a parapet over which the flames will have difficulty in leaping. We sometimes find that a wall is carried up three feet above the roof but the cornice is run continuously along the front from one building to another. The cornice should be cut as well as the roof.

We call for increasing thickness of walls as the building increases in height, and that the ledges formed by the increase in thickness shall bear the floor joists. This is very important as we are constantly finding that the practice of inserting joists in the walls by leaving out a couple of bricks, not only conveys fire through the walls should the adjoining building burn, but also when a serious fire occurs in the supposed building under consideration, the falling of the floors brings the walls down, causing a total loss to it and to its contents, and also lets the fire through into the next building.

Party walls require to be four inches thicker than independent walls, the reason for which I am sure will be apparent to every architect. There are many party walls erected in which the joists have only four inches of brick between their ends, and in some cases the joists actually meet and overlap. Such walls are hardly worthy of the name.

The schedule imposes an extra charge on the building if a large amount of the front is of glass or wood, and the charges for exposure to a building so constructed, are also increased.

Our standard calls for a building of moderate height; if that height is increased, extra charges are imposed.

There is a small charge for wooden cornices on building, but such increase the charge for exposure from the adjacent buildings and should be avoided as much possible.

The standard ceiling is plaster upon wooden lath, or a ceiling of metal. There is of course no objection if an old ceiling of plaster upon lath, is covered with metal.

Wood for sheathing of walls or ceilings is decidedly objected to, and still more so if the wood be varnished, the charges in that case being doubled. With wood at its present price there is no economy in using such inflammable material for partitions or ceilings, and the insurance companies hope that such will soon be a thing of the past. If metallic lath is used throughout the building instead of the ordinary wooden laths, a reduction is allowed.

The standard calls for floors to be three inches in in thickness. If they are thicker than that, an increased deduction is allowed for each inch in excess. It is recognized that there are very few floors that exceed two inches in thickness, and so in applying the charges, there is a deduction allowed for every inch in excess of two inches.

Then again, if the floors are double and if they have metal between, or if the floors are made water-proof, and drained to carry off any water thrown upon them, or if the floors are made fire-proof, that is, of steel and concrete construction, with the steel properly protected by metal lath and plaster, or porous tile, deductions are allowed.

If the area exceeds the standard, there are extra charges, but even in this case if there are numerous brick walls sub-dividing the building, the area charge is reduced. It is very difficult to locate a fire which may originate in a building of large area, as the smoke at once fills the whole building and when the firemen arrive they waste a large amount of precious time in endeavoring to get at the exact spot where the stock or building is burning.

When the Murray store burned, the building was filled with smoke and the firemen could not see what they were doing; they found after they had been working for two hours that they were throwing the water against a brick wall, the fire being on the other side of it. This does not happen in a small store, or one which is divided into sections.

Now let us suppose that a building has been constructed with solid walls, with double floors, that metallic lathing has been used throughout the building, and what has been gained if numerous openings from floor are introduced?

I would like to draw your attention to Robert Simpson's building on the corner of Queen and Yonge streets, one of the best examples of fire proof construction in the city. In it there is an immense light well from cellar to roof. There are also openings from floor to floor for stairways and elevators. A fire starting in that building would have every opportunity to spread from cellar to roof in an incredibly short time, and if such did happen it would be found that the fire-proof building was nothing more than an immense stove in which the contents would be speedily and completely consumed, although the building itself might remain comparatively unhurt. Were it not for the introduction of automatic sprinklers such a risk would probably not be insured for less than 5% per annum,

and even at that rate the insurance secured would in all probability be but a fraction of the value.

The insurance companies recognize the difficulty of providing an absolute cut-off between floors in a mercantile building, but such is possible, either by having a fire-proof elevator and stairway annex cut off from each floor by fire-proof revolving doors, or if the elevators and stairways must be in the building, then in a shaft walled in by metallic lath and plaster, and (or) wired glass. Well holes or light wells can also be closed by wired glass either perpendicularly around the shaft, or horizontally at the floor line, or better still, construct the building so as not to require such at all. If elevators and stairways are introduced, the companies must charge for them, the charges being so fixed that even if the owner cannot entirely remove the hazard, that the companies will make some allowance for a partial protection.

In this connection let me give you an illustration. If a property owner were to erect six stores alongside of one another, each, one story high, with a brick wall in rear and in front and at each end, but with only lath and plaster partitions between each store, everyone passing would say; that is a shell; that is no better than a frame building; that is a fire trap. But if we can imagine the supposed property owner turning the supposed block of stores upon end so that the first store to the left is the first storey of the new building which is six stories high, and if the supposed property owner immediately starts to make openings between each of the lath and plaster partitions, inserting stairways from floor to floor, and also introducing an elevator from cellar to garret, the passer-by looks and says, that is a splendid building.

We require that skylights be of wired glass in metal frame, and where so built there is no charge. A skylight of thin glass in wooden frame is a conflagration breeder. It not only assists a fire inside but invites the outsider to come in.

Heating by hot air furnaces and by stoves has cost the companies a tidy sum and such is charged for.

Chimneys should not be placed on brackets. Such is a dangerous expedient; if it must be resorted to, a charge must be imposed.

The mansard roof is an undesirable style which is rapidly disappearing. Where such is constructed it necessarily means that a large amount of wooden material is placed in the most dangerous position in the building—hardest to reach should a fire occur, and the point to which all flames naturally go whenever a fire breaks out. Such a roof either entails the destruction of the building or a very serious loss, owing to the amount of water required to extinguish a fire in it.

Many buildings are constructed with blind attics. Such should be avoided wherever possible; particularly should great care be taken that there is no opening from an elevator shaft into a blind attic. Such condition is frequently found and is exceedingly careless and dangerous.

A good many buildings are still roofed with shingles. It is hoped that the architects of Toronto will use their influence to discontinue the use of this most dangerous roof covering. Numerous conflagrations can be traced to the fact that the buildings had shingle roofs. Such not only burn rapidly themselves, but set fire to others, and after a fire has been burning a short time, the shingles will rise from the roof and fly like birds to a considerable distance.

If internal protection against fire is provided, there is an allowance made, particularly for casks and pails, which any workman or even child, knows how to use, but the companies place their chief reliance on the speedy arrival of the fire brigade, and also that the construction of the building is such that the fire will not have been able to gain undue headway before the brigade arrives. If the building is constructed with open elevators, open stairways, or open well holes, a fire will spread with great rapidity from cellar to roof, and by the time the brigade will have reached the scene, the flames will probably be breaking out of every window and cannot be stopped by any brigade short of almost a total loss. If the elevator had been trapped, the stairway or well hole closed, the fire would probably be still burning upon the floor in which it originated, and the firemen would have a fair chance to extinguish it.

It may be of interest to the architects to know that the Mercantile Schedule which we are to discuss this evening, is based on a schedule compiled a few years ago by a large committee composed of the leading underwriters in the Eastern States, who after more than two years of conference and committee work, published the Universal Mercantile Schedule. I have a copy of this schedule here and can procure others if your members desire to have them for reference.

This work is the basis of the schedule we have adopted in Canada. It will I think repay any time an architect may devote to its study, and I take the liberty of commending it to you to-night.

I may also point out that the schedule referred to has not as yet been put in force in Toronto, and may not be for a few months or even a year. Anyone however, who is about to build would be wise to comply with the requirements of the standard.

The schedule recognizes that a building may be well constructed and still be used in a careless and dangerous manner, and so there are charges for "Faults of Management," such as unprotected stove pipes through floors or partitions—unprotected floors under stoves—bottom of elevator shaft used as a waste dump—swinging gas brackets—badly placed heating furnaces, and dangerous fire places.

The last charge for crowding and overloading the building will, I am sure, appeal to all here as a direct incentive to tear down and build greater.

I am afraid you are all weary of this subject, which I regret I am not able to make as interesting as a critical dissertation on the colonial style or some other one equally fashionable, but I am nearly through now and merely wish to direct your attention to some features of our charges for exposures.

A study of conflagrations in cities shows that they are generally caused by unprotected openings in adjacent walls, a fire being enabled by such to spread quickly to several adjacent buildings and soon provide the brigade with a job quite too large for their fire-fighting equipment. Care should therefore be taken by the architect to guard against this danger, and when there must be numerous window openings in a wall facing another similiar wall a few feet distant, that such are protected by outside shutters of wood covered on both sides with metal, or have a metallic frame and wired glass in each exposed window, or provide a water curtain. Also if possible, avoid having the windows in one wall directly opposite the windows of the other. This can often be easily arranged.

Do not cut off a one storey section by a solid wall on the ground floor and leave several windows in the higher building looking down upon the roof of the lower one. Avoid heavy wooden cornices, and if there must be an overhanging eave, see that it is covered with metal. In Montreal a very popular form of roof is centre drained, such not requiring any projecting eave. Also avoid breaking division walls between buildings. It is astonishing to what an extent this practice has grown, until we sometimes find that in as many as ten adjoining buildings there is not one party wall absolutely intact.

If party or division walls must be cut, then be careful to leave no wood about the opening, which should be arched and provided with a sill of stone or concrete, while the door to close the opening should be really and truly standard—such, properly hung on an incline are less in the way, and less unsightly than the old hinged door.

The insurance companies in adopting this standard, hope that it will induce more careful planning, more solid construction, fewer fires, and lower rates. The standard should be of service to the up-to-date architect and we hope it will be freely used by you all in persuading the property owner that good construction and good returns go hand in hand.

THE NOVA SCOTIA FREESTONES.

The changing fashions in stone used for building purposes in all the large cities of America have called out many comments, not alone from practical stone men, but also from general writers who are impressed by the varying effects of city architecture. The brownstone fronts of New York, which formerly lined street after street, with their stately, if sombre facades, figure in every description of the city. As the brownstone yielded place to other materials, every visitor to the city felt called upon to record the change. About a generation ago one stone, although in several colors, was largely used in New York and in all of the leading eastern cities. It has everything to commend it; beauty of color, fineness of texture, ease of working and durability. But its reign was comparatively brief. After a few years of high favor, it passed almost wholly out of the market and now scarcely a foot of it is used in New York and but very little in any of the American cities. Perhaps one reason for this is that it was not an American stone and that our architects and builders thought that they should give the preference to a native product. This was the Nova Scotia freestone. The buildings in which it was used that are still standing afford striking testimony of its excellent quality. About 1865 Mr. Charles D. Archibald furnished the Nova Scotia sandstone in what is known as the olive color for the wall around Central Park. This stone came from the Mary's Point quarry in New Brunswick. Stone in a wall like this in such an exposed position does not have the protection from the weather that is afforded by a building, but this has lasted admirably and few freestones would have endured as well.

About three or four years later one of the first building jobs in the Nova Scotia stone was the Dry Dock Savings Bank on Fourth Avenue, which is still standing. This stone was furnished by the late G. P. Sherwood from the "Budro" quarry on the Petit-Codiac river in New Brunswick. Mr. Sherwood also furnished the stone for the old Hanover bank building, on the corner of Pine and Nassau streets, recently torn down to make room for the new twenty-two story structure of pink Milford granite. When the old building was destroyed it was seen that the stone had weathered perfectly, that every arris was as sharp as when originally cut and that the carved work still bore the mark of the chisel. Many other important buildings were erected of this stone, among them being the block at the corner of Forty-fifth street and Sixth avenue, from the Sherwood quarries, and the Sloane building on Broadway, of brownstone from Mary's Point.

In the New England cities the Nova Scotia freestone was held in still higher favor and its general use by the architects and builders continued for an even longer time. Among the notable structures in Boston which made use of either the russet or olive stone were the Fifty Associates building on New Washington street, the Harvard buildings on Arch street, the Boylston Bank building, the Young Men's Christian Union on Boylston street, the Columbus Hotel, Parker Memorial Hotel, Hotel Commonwealth, Dr. Lothrop's church, Providence and Lowell depots, the Catholic Cathedral on Washington street, and Prof. Agassiz's Museum, besides many imposing blocks of dwellings and business houses.

Although there has ceased to be any considerable market for this stone in the States, it is in good demand throughout Canada. There is every reason for this aside from mere local pride. Some of the quarries have been worked for a great many years, but the amount of high-grade stone that is still available is unlimited. In a few places quarrying is conducted at a disadvantage. On the River John and the River Philip, most of the quarries are below the river level. The method of working them is to build a dyke or dam along the shore, pump out the water within and then open a quarry. The objection to this method is that it is impossible to keep the water out at all times and it is well known that salt water has a very deleterious effect on sandstone. It frequently causes it to scale or chip and at the best it almost certainly leads to efflorescence. So general is this fact recognized that when the stone used to be shipped to the States on barges the dealers insisted upon its being stowed in the hold and would not purchase it if it made the sea voyage on the decks. At Wallace Harbor the quarries are admirable, having level beds capable of furnishing fine platforms. The stone is overlaid with from 12 to 20 feet of stiff clay. This is a peculiar formation and has almost a leathery toughness. It has to be removed with a pick. At Kennetcook is found a dark brown and an olive and a blue grit, the latter of which is used for grindstones. A cargo of this grit was sent a number of years ago to the water shops at Manchester and other place in Great Britain, and the workmen declared it made the finest grindstones they had ever used. For some reason no great industry was ever built up at this place. Manuidie was also another place that was famous for its grindstones and scythe stones. These deposits were worked for many years by the Seaman Brothers, whose name was known throughout the world.—Stone.

THE BUILDERS' FOREMAN AND CLERK OF WORKS.

At a recent annual dinner of the Provident Institution of Builders' Foremen and Clerks of Works of Great Britain, the chairman, Mr. F. Higgs, thus described the qualifications of a successful builders' foreman and clerk of works—"Every good foreman should be careful, accurate and shrewd, and should have patience, forbearance and tact, personal magnetism, organizing power, fidelity to duty—in fact, character. The Clerk of Works should be honest in purpose and action, disinterested, fair and unbiased in judgment, open-minded for new methods and ideas, not wanting in a due sense of proportion and able to see two sides to a question. The ideal foreman and clerk of works did not quarrel, but pulled together, for though there might be two ways of looking at a work, it must not be forgotten that there was only that one work."

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO. of Toronto, Limited, Publishers,

Confederation Life Building, - - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1903.

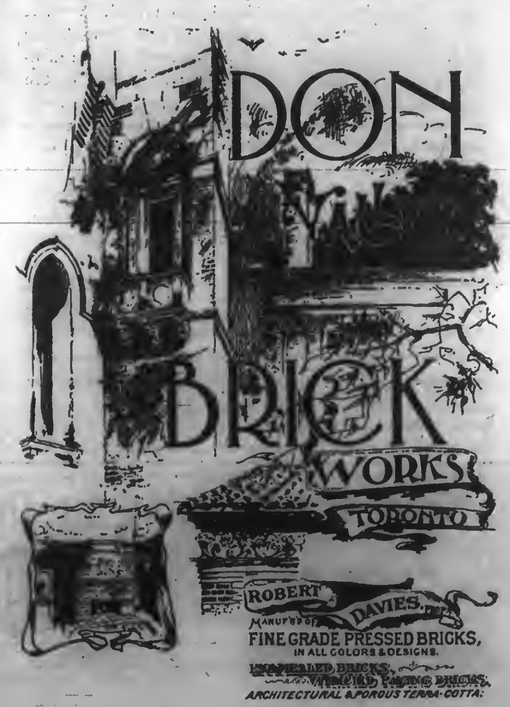
E. W. WHITTINGTON	Secretary
THOS. CATTERALL	Treasurer

NOTES.

It is stated that during one month recently, nearly 100,000 tons of iron and steel material were imported through the three ports of New York, Philadelphia and Baltimore. The shipment included pig iron, steel billets, steel and iron rails, structural steel and wire rods, and plate bars. The immediate demand for such products is so great that the domestic plants, extensive as they are, cannot meet it.



MEN WHO BUILD A SKY-SCRAPER.

According to the Architects' and Builders' Journal the following staff is employed in the erection of a modern sky scraper :—

Laborers	300
Carpenters	100
Concrete layers	30
Riggers and riveters	150
Stone-masons	15
Tile layers	30
Electricians	30
Plumbers	20
Bricklayers	20
Plasterers	50
Marble workers	20
Housesmiths	25
Painters	25
Steam-fitters	25
Roofers	30
Sheet-metal workers	20
Elevator workers	30
Boiler and engine erectors	30
Mail-chute workers	10
Stationary engineers and firemen	10
Total	970

PERSONAL.

A partnership has recently been formed between Messrs. G. W. Grant and A. E. Henderson, architects, of Vancouver, B. C.

Mr. L. Feystore, builder, and a resident of Toronto for thirty years, died in that city recently following an operation for appendicitis.

Mr. Silas E. Hoidge, a well-known and highly respected builder of Toronto, died in that city last month as the result of a fall from a building on which he was working at Toronto Junction.

Acknowledgement should have been made in our March issue to the publishers of La Presse, Montreal, to whose courtesy we are indebted for the use of the plate from which was printed the illustration of the Polytechnic School.

The Building Contractors' Council, of Chicago, have determined to sign no agreements with Unions that do not contain a clause prohibiting sympathetic strikes, limitation of amount of work a workman may perform in a day, or that do not permit the unlimited use of machinery, the employment of apprentices, and the right to employ or discharge any workman at pleasure.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingles stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

Stained woods and descriptive literature sent free upon request.

TERRA COTTA FIREPROOF BUILDING MATERIAL

POROUS TERRA COTTA among underwriters is classed as preferred risk, and the schedule of rates now enforced in the city of New York shows a difference, often great, which, computed means an annuity on large sums of money.

This indisputable fact appeals to architects as representing clients who may soon be exposed to the same classification in Canada. An apparent saving in selecting cheaper fireproof material may be more than lost through increased insurance cost.

POROUS TERRA COTTA FIREPROOFING is a credit to the buildings in which it is used and increases their selling value.

The **Montreal Terra Cotta Lumber Company,** Limited,

N. T. Gagnon, Selling Agent, 204 St. James St., Montreal, Canada.

ADVERTISING VALUE.

It is very well for some men to say they believe in advertising, and to expect a liberal return from their investment merely as a reward for their faith in the value of publicity. It is quite another thing to get value out of the space used. The belief in advertising is natural since advertising has done much for many establishments and individuals, but it will not do much unless much is put into the advertising. The real secret about business is business, and the real worth of advertising depends on business also. It is necessary to put common or uncommon business judgment into the space used for the benefit of the business and to make the establishment, the goods and the methods stand out before the possible customer in a light which will be pleasing and help the public in general to understand the worth of the stock. There are those who talk ethical advertising and ideal publicity to an extent that they really believe in it themselves, but will be disappointed in results unless they get something into that advertising which will give it vitality. It is useless to expect to impress a public with the standing of a firm as an up-to-date business combination unless there be life in the advertisement. The message must show the strength of the merchant behind it and must demonstrate the merits of the place. The point is the life and character of the announcement. Make it stand out in every line and make it so conspicuous that any possible buyer will see it and appreciate it.—Advertising World.

NOTES.

At Upleatham, North Yorkshire, is said to be the smallest church in England. Its size is 17′ 9″ x 13′. The building which is 900 years old, is now used as a cemetery chapel.

An International exhibition of building materials and methods has been arranged for at Paris this year. The date of opening has not yet been announced. Great Britain, Germany and Belgium will be well represented. A leading feature of the British and Belgian exhibits will be plans for low cost dwellings.

Upwards of twenty committees and subcommittees composed of persons prominently identified with the iron and steel industries of Great Britain have been engaged for a considerable time on the work of standardizing structural iron and steel sections, equal, unequal, and bulb angles, bulb tees and plates, H beams, Z and T bars, channels and beams. Thirty sections of H beams are given, varying from 3in. by 1½in. to 24in. by 7½in., and weighing respectively from 4 lbs. to 100 lbs. per ft. The Engineering Standards Committee states that beams ordered to the standard thickness shall be practically accurate in profile; but if the thickness of the web is less or greater than these standards, the width of the section will be decreased or increased by the same amount; and it is suggested that beams be ordered by depth of section, width of flanges, and weight per foot. It is claimed that the standardization of sections will effect a saving of several million pounds annually.

William Clendenning writes in "Fireproof" on the subject of "Misplaced Fire Escapes." He states that hundreds of fire escapes in our principal cities follow window lines vertically, from top to bottom, thus exposing them directly to the action of fire when it bursts from the windows at each floor, rendering the escapes unsafe and unfit for the exit of any human being, because they become red-hot in many cases, thus making them death-traps rather than fire escapes. In the course of a single street car ride in Chicago the author says he counted on one side of the street sixty-five fire escapes so located as to be utterly useless in cases of fire on either side of the lower stories. The remedy for this alarming state of affairs is to place the fire escapes at or near a corner, or at least removed from immediate proximity to windows, with platforms communicating at each floor, and so give the tenant a chance for his life. This subject is probably new to most people and should be looked into by building inspectors. A fire escape placed in front of a row of windows should be condemned and the owner required to remove it to a comparatively safe position.

John Mackay & Coy., of The Canadian Bank of Commerce Building, Toronto, would like to be placed in communication with a firm of architects of the highest professional standing, and of special experience in the erection of modern Bakeries. Communications will be held in the strictest confidence.

LIGHT

The "Best" Light

Brighter than Electricity or Acetylene and Cheaper than Kerosene

Makes and burns its own gas. It is portable. Requires no pipes, wires or gas machine. A safe, pure white, powerful steady light. 500 candle power costs 2 cents for fifteen hours. Permitted by Fire Insurance Underwriters. No wicks to trim, no smoke or smell. Saving effected by its use quickly pays for it. Over 100 styles for indoor and outdoor use. This is the Pioneer Incandescent Vapor Gas Lamp. It is perfect. Beware of imitations. Agents wanted everywhere. Every lamp warranted. THE BEST LIGHT CO., 225 East Fifth Street, Canton, Ohio.

Scarcity of Slate.

Unusual activity in building construction coupled with difficulty in securing skilled quarrymen are believed to be the principal causes of the present scarcity of roofing slates. Scarcity of skilled labor in this line also prevails in Wales, so that no workmen can be imported with which to extend operations on this side the Atlantic. The past winter is said to have been an unfavorable one for slate quarrying operations, frequent thaws and rains causing the loss of large quantities of material. If the necessary labor can be obtained this should be a favorable time for the development of the extensive slate deposits in Newfoundland, as prices are said to be higher than at any period during the last twenty years.

The Colonial Style Run Riot.

We are pleased to note the tendency in the United States to substitute for the Colonial style in domestic architecture; half-timber and other forms of construction following closely the best English examples. The supremacy of English house and church architecture cannot be doubted, while the so-called Colonial architecture of these days has become an abomination. In some of the newly built up residence districts of Toronto and other Canadian cities may be seen whole streets of houses, the fronts adorned with porches and verandahs of the so-called Colonial style, each being an exact duplicate of all the others. The effect is monotonous in the extreme, and the person who is obliged to look on these houses day after day learns to abhor white porches and verandahs. True, these serve a useful purpose in our climate, but why should there not be variety in design and material, thus imparting to them individuality and interest? Of course they could not then be designated Colonial, but they would be none the worse for that.

Protection of Buildings from Lightning.

The Committee of the Royal Institute of British Architects and the Surveyors Institute appointed two years ago to investigate the subject of the protection of buildings from lightning, expect to present their report at the close of the present year. Meanwhile some details have been given out of the reports already sent in by the committee's observers. These contain a list of sixteen protected buildings struck by lightning and more or less seriously damaged, including a considerable number of churches, lighthouses and factories. One of the most interesting cases so far reported, and one which seems to show that the so-called protectors sometimes tend to induce lightning stroke, is that of a large country house in Sussex, erected some twenty-eight years ago, and till recently without any form of protection. In 1901 a church in the immediate neighbourhood having been struck, the owner of the house, for greater security, decided to have lightning rods put up. An elaborate system was installed and completed in March, 1902, nearly every portion of the building having its own finial and conductor. During the storm season of last year the house was twice struck—on June 17 and

August 8. On each occasion, besides other injuries a chimney stack was damaged, the brickwork being split up and the capping-stones dislodged and hurled about in all directions. The lightning-rods on the damaged chimneys were torn from their supports and much bent. Careful study will be given by the Committee of all the cases reported, and an effort will be made to suggest better methods of protection than those at present employed.

Over-Production of Cement.

The losses arising from over-production in the manufacture of Portland cement in Great Britain and Germany have already been alluded to. From data recently published it appears that in Russia from the same cause the industry has also become unprofitable. Until 1896 there was only one cement factory in Russia, the Black Sea Company, a German concern, at Novorossik, with a yearly output of 30,000 barrels. Two years later owing to increased demand, there were eight factories. In spite of the fact that the consumption of cement rose from 409,000 barrels in 1896 to a million and a half barrels in 1901, the rapid increase in manufacturing capacity forced prices down in 1900 to a point where the older factories paid no dividends and the newer ones suffered heavy losses, and in some instances were obliged to go out of business. Efforts are now being made to put the industry on a paying basis by forming an association of the manufacturers to control prices and by manufacturing at home the cement casks which heretofore have been imported from Poland. There is a lesson in all this for the present manufacturers of cement in Canada and more especially for persons who contemplate engaging in the business. The manufacturing capacity in this line has increased very rapidly in Canada within the last five years, and has almost if not quite reached the safe limit. Notwithstanding the greatly increased demand of late for cement for construction work in which other materials were formerly employed as well as for new uses, manufacturers of cement should take warning by the experience of the countries we have mentioned, and be careful not to let the supply outrun the normal demand.

Defensive Methods of Employers.

There is a growing disposition among employers of skilled labor to co-operate with each other in resisting the ever growing and intolerant demands of organized labor. It is beginning to be understood that if employers are to have any rights whatever or any control over the businesses to the building up of which their capital and best efforts have been devoted, they must stand together and support one another in a more determined manner than they have done in the past. The benefits of such co-operation received illustration recently in one of the smaller cities of Western Ontario. The union workmen in the employ of a contractor struck work because some fault had been found with them. They were aware that building mechanics were being advertised for by some of the other local contractors who were expected to welcome them. Their former employer, however, advised his fellow contractors by telephone of the circumstances of the case, and when the strikers applied for employment they were invariably met with the reply that no help was required. This had the effect of reducing their arrogance and they returned to work. Another case was that of the Penberthy Injector Co., of Detroit, to whom the alternative was presented by the Brass Workers' Union of discharging a non-union workman or contending with a strike. The Penberthy Co. brought the facts to the attention of the principal manufacturing firms of the city, forty-seven of which met and passed a resolution asserting the equal right of every man to employment, and pledging their support to the Penberthy Co. in resisting the unjust demands made upon them. It is understood that a movement is now on foot having for its object the organization of employers of labor throughout the province of Ontario.

No Outside Interference.

A strong protest has recently been entered in several quarters against interference with and control of Canadian labor organizations by the leaders of the International Unions of the United States. Archbishop Bruchesi recently caused to be read a pastoral letter in all the Roman Catholic churches of Montreal, urging Catholic workmen to keep clear of entangling alliances which would make them subservient to the mandates of foreign organizations having little knowledge or sympathy with the conditions existing between employers and employes in this country. The letter goes on to say: "Calmness and reflection will make you realize that there are just limits to your demands. You cannot reasonably expect that the workingman's wages will be ever on the increase, and that at the same time the hours of labor will decrease proportionately." In the Senate at Ottawa a discussion recently took place on this subject in connection with a Bill to amend the Criminal Code respecting offences connected with trade and breaches of contract. Hon. William Gibson was not opposed to labor unions per se, but objected to foreign dictation. He referred to a case in Hastings County where a company was wiped out by a strike ordered from Washington. Almost every labor union was directed from Washington. He advocated prohibiting international unions. They would effect settlements more easily, and have fewer strikes. He hoped the bill would be made so that they could indict the lodges. He read a letter received on May 17 from the Beamsville branch of the Journeymen Stonecutters' Association of North America, demanding $3.50 a day for nine hours. The letter went on: "We have been notified by the Niagara Falls branch not to send stone into their jurisdiction." He was not only told what he was to pay the men, but that he must not cut stone to be used in another jurisdiction. He hoped the bill would be enlarged, so as to make the men amenable to the law, and strike at the root of the matter. Hon. James McMullen said it Canadian labor organizations were to be controlled from the United States, Canadians would be unable to take contracts, because they did not know when a strike might be ordered. If some American institution was desirous of crippling a competitive institution here, all they had to do was to approach the head center, tip them the wink, point out how a service could be rendered. A strike would ensue, and the Canadian owner would be the loser. He was surprised at the attitude of the press. There did not appear to be a paper in Canada that had the courage to come out boldly on this question.

DADO DESIGN BASED ON LILIES. FROM "PLANT FORM AND DESIGN."

APARTMENT LIFE.

The growth of the apartment idea is not an unmixed gain. There are few more important words in the English language than the word "home," and it is about to acquire but a modified meaning to those persons who intend to adopt a life in the apartment houses that are beginning to rise in our big cities.

Home is a place which shuts off the world at the street door; a place must be separate, self-contained, and in some sense our own to give properly the feeling of home; and an apartment is these things only in a modified sense. It is little more separate or self contained than a suite of rooms in a boarding house would be; and proprietorship in an apartment, even if held by purchase, cannot compare with the proprietorship which extends down to the ground and includes some portion of it. A lodging in the air is not perfectly a home "barring you're a bird."

In the second place, though home to be home must shut its inmates off from the world, it must also, for people of refinement, provide for their separation from one another. The essence of house planning is in the effort to keep functions and people apart. The upstairs and downstairs arrangement of a house gives a definiteness for this purpose which one never realizes so clearly as when looking over a "flat." On a level, particularly when, as so often happens, it is made necessary to pass all the bedrooms on the way from the entrance to the living rooms—privacy is more difficult. A delicate woman, who wishes to lie down during the day, imposes restraint on all the inmates; or else becomes accustomed to less consideration than she would receive in a house. There is too great nearness of the inmates as a matter of feet and inches, and this is likely to result in too little distance in the matter of relations with one another. A delicate woman is apt to become indelicate woman in the matter of appearances in dishabille, which the comparative privacy given by the different levels of a house should prevent.

The ideas of home and family are closely connected, but what is to be done with children in a flat? There is no upper room where they can play and make as much noise as they like; nor is there likely to be any ground outside, and if there is it is public ground. This is not the same thing as ground, however small, apart from the rest of the world, where children can have room for their own numerous private affairs. A very simple habitation, if it has room for these, will, to a family of children, be dignified by all the sentiments which home inspires; sentiments which make childhood a memory and prepare the way for the domestic and patriotic ideas with which it is so important that the manhood and womanhood of a nation should be possessed. Large families are in themselves the making of a home; but what is to be done with a large family in a flat? What was always a troublesome joy is likely to preponderate so much on the side of trouble as to cease altogether to be a joy; and then there is danger of it's ceasing to be at all. The happiness of a woman does not seem to consist now as it did in the early days of the world, in being the mother of children. Domestic life has ceased to be to her her necessary field of work. Men, much as they hate work, do seem to acquire a sort of enthusiasm for the proper fulfilment of it; it is their life. But women seem not to regard domestic duties as their life, but as an irksome addition to their life. Their confabulations about it have a tone of discontent. They incite one another continually to desire greater freedom from care. The woman who is most envied is she who has the least care. Not only is pride in their families vanishing but pride in their housekeeping as well; and apartment life will complete the process. With no families and almost no housekeeping—for, with soup in paper boxes and fried potatoes in a bottle, a woman has little to think of now if she has credit and a telephone—with nothing to do at home, women may fulfil their ideal; but will they not also fulfil the warning of St. Paul and "learn to be idle, wandering about from house to house; and not only idle, but tatlers also and busybodies, speaking things which they ought not."

It is pertinent to enquire whether the solution of the housing question, most suited to our national traditions and character, does not lie in radial railways, that will enable us to keep touch with the town while spread over the country, rather than in a system of housing that will pack us, six or eight families deep, over so much land only as is comprised within the area of a concreted cellar.

The essence of the question is in reality the necessity of giving children an opportunity for outdoor life at home. Playing grounds are all very well as a remedy, but we should avoid the extremity that requires them. It has long been a subject of lamentation that the poor and the children of the poor should live and play on the street; it will be lamentable indeed if the children of the comparatively well to do are brought to the same condition. This extreme as well as the other is exemplified in New York, and should furnish a warning to aspiring cities. In New York, a long way up, in the Harlem neighborhood, the streets on which the residential flats are built are full of respectably dressed children; running about in the road among the horses, sitting on the dirty sidewalk, playing ball over the heads of the passers by. One receives an impression that they have just got out of school and are lingering before going home. The discovery that they have got home, that this is their home, gives a shock when it is first realized. All the streets in the neighborhood exhibit the same state of things. A little investigation

shows that it is unavoidable. A popular flat, only six storeys high, with a hundred feet of frontage; inhabited by marred people chiefly, clerks of some standing; a lawyer or so, a couple of doctors, and people of that sort; shows on its plan but scanty accommodation for children. Most of the apartments have one bedroom or two; none have more than three. Yet, when the rooms available for children are counted up, there appears without squeezing, and there must be a good deal of squeezing done in these apartments—possible room for fifty children. Across the road there is an apartment building of similar size, and others all along the street. This simply means that the children in that street might line both sides of the road; that, if they all played at home, the hundred running feet of street in front of the apartment building examined might have to suffice for the playground of a hundred children. It is not likely there are so many; but that is an evil on the other side, for there ought to be twice as many. It looked a miserable state of affairs. "Boys" John Boroughs says "live in a world that is inhabited entirely by boys;" but the boys in these streets must have another view of life thrust upon them, and perhaps this may have something to do with the elderliness of the American boy, about which his fellow countrymen sometimes complain.

There seems to be a tendency to hail the advent of apartment house building as a solution of every difficulty; but there is evidently something to be said on the other side. If they were regarded only as a final necessity; as something to be avoided as long as there is any other way of convenient housing; it would probably be nearer the truth, and we should turn our attention first to what is more really a development of our own times—the application of the means of rapid transit to enable men who work in the city to live in the country where land is cheap.

W. A. LANGTON.

FIREPROOF FLOOR CONSTRUCTION.

Mr. Frank Caws, F.R.I.B.A., recently gave an address on "Fireproof Floor Construction" before the Edinburgh Architectural Association. Referring to the modern use of Portland cement and iron in floor construction, Mr. Caws said that generally speaking the introduction of steel girders as supports for the concrete has been carried to a very unwise excess, inasmuch as the action of fire upon the steel, causing it to expand, made it most injurious to the concrete floors, and, instead of being a support, it proved in such cases the means of their destruction. Therefore, he advocated a method of constructing floors in large slabs of concrete, with a minimum amount of steel bearers, so disposed and protected from the fire as to give the necessary support without introducing an element of weakness. In this connection the results have been published of a test of two hours duration in October last by the British Fire Prevention Committee of a floor of fire supports and oak flooring. The floor was 22ft. 3in. by 10ft. in the clear, and consisted of two 10in. by 12in. beams of yellow fir placed across the testing-hut, with four 10 in. by 10 in. joists notched into them at 2 ft. 6 in. centres, oak boards 8½ in. wide and 2½ in. thick being spiked on top; a 15 in. by 15 in. yellow fir post supported the floor in the centre. The floor was loaded with 232 lbs. to the square foot, distributed. In 4 minutes smoke issued from the joint between the parapet-wall and the oak flooring. In 89 minutes flame first came through the floor. In 109 minutes a small portion of the oak flooring fell. The post, beams and joists were considerably reduced in size and charred, the post to a depth of about 1¼ in. and the beams and joists about 2 in. The average temperature of the fire was about 1,400 degs. Fahr.

"SLIP-SHOD TENDERING."

To the Editor of the CANADIAN ARCHITECT AND BUILDER:

Sir,—In reference to your April article "Slip-Shod Tendering," I wish to say that contractors are not alone to blame for this. They are often asked to submit tenders for work which is not clearly described by either drawings or specifications; probably no lot grades are given and sewers and drains which must be connected with, are not located. In many cases several alternative figures are asked for different designs and finish. Now under these circumstances, a contractor must spend considerable time and perhaps money in preparing an intelligent estimate. If quantities were supplied him or compensation for tendering, as is done in some countries, the case would be quite different. As it is however he frequently finds that he has spent his time (which is the same as money to most contractors) for nothing, not even a chance for the job, which either does not go on at all or goes to a previously selected builder, estimates being asked for simply to set the price.

In my opinion these are some of the reasons why contractors are tempted to do so much guessing and why this will continue until such time as both architects and builders are organized to that extent that they can compel clients to pay a fair price for valuable information.

An architect should be competent to estimate to within 10 per cent. of the cost of most buildings; close enough at least to enable his client to decide when and what to build. To call upon perhaps a dozen busy men to give their time gratis to help to decide these points is scarcely honest.

Yours truly,

A. C. C.

VANCOUVER, B. C., May 18, 1903.

A POSSIBLE SOLUTION OF THE SKY-SCRAPER QUESTION AS BEARING ON THE SUBJECT OF CITY HYGIENE.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

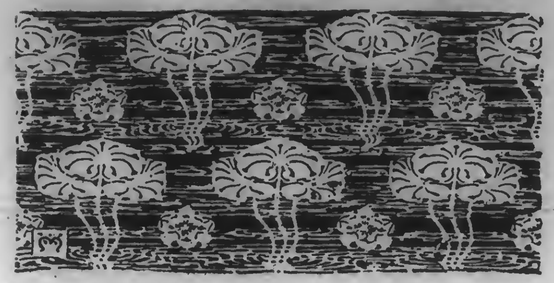
SIR,—Mr. Langton's pertinent treatment of the question of "High Buildings" in your last issue leads me to suggest a possible way out of the dilemma might be for Manhattan and other cities to legislate in a way to limit them to two out of every three of the buildings forming the line of the street tenements.

Two tall buildings could thus adjoin each other—the lots supposed to be some 25 to 30ft. frontage, more or less—leaving a space between for light and air. In this way each of the taller structures could have windows along one side or party wall of the building. This would form a not objectionable crenelated series of tenements; the vertical protuberances starting from above the 5th, 6th or 7th story of the row of structures, according to width of street, as along the Paris boulevards, with a continuous cornice or entablature at that height.

Each proprietor of a high building adjoining the lower structure, should be bound to equalize advantages by making over to the proprietors of the low or stinted block, one-third of the net profits derivable from the upper stories of the higher structures after duly allowing for interest on net cost thereof, and other charges considered fair in the premises.

CHAS. BAILLAIRGE, C. E., Quebec.

Professor Ramsey, in a lecture at Carpenters' Hall, London, said that it is a common practice to attempt to hasten the drying of new buildings by leaving the doors and flues open, but he thought it would be more rational to close these vents, and to use charcoal braziers in the closed rooms. The hot gaseous carbonic acid evolved from the burning charcoal would flow through the walls, and the carbonic acid would materially accelerate the conversion of the lime in the mortar into carbonate of lime; the passage of the hot carbonic acid through the walls would not only dry out the water, but would increase materially the rate of conversion of the lime into carbonate of lime.



WATER-LILY STENCIL FOR WALL HANGING. (FROM "PLANT FORM AND DESIGN.")

BY THE WAY.

The latest specimen of "tinsel" architecture, of which alas! there are already too many examples, is reported from California. The builder of a frame house is said to have applied to the exterior while the paint was still wet, a rough-casting of sand and fine blown glass.

× × ×

The purchaser of a furnace sued the manufacturer to recover the price, alleging that the furnace would not perform the guaranteed duty. In proof that the furnace was a poor heater he cited the fact that while it was being run to its full capacity, a barrel of beer placed on top of it had frozen.

× × ×

A factory is to be established at St. Mary's, Ont., for the manufacture of Portland cement. The intention is to use in the process crushed limestone instead of marl. The promotors of the enterprise claim that by this means the cement can be produced more cheaply than by the method now employed.

× × ×

George Ley, whose luck at cards was proverbial, resolved to build his residence at Combe Martin, North Devon, England, in the form of a pack of cards, split up and erected castlewise. The idea was carried out thoroughly and the edifice equipped with fifty-two windows—one for each card—while its form necessitated a plethora of chimney stacks.

The visitor to Washington is delighted with its clean streets, its extended boulevards, resembling those of Paris, and its magnificent public buildings, especially the Capitol, the Art Gallery and the Congressional Library. The latter with its beautiful mural decorations is alone worth many hundred miles of travel to see. The domestic architecture of Washington, with few exceptions, is however, the most commonplace of any that I have visited in the United States. We have been accustomed to believe that a few good examples of architecture placed about a city must tend to leaven the whole architectural lump. If that be true, Washington must be regarded as the exception which proves the rule.

× × ×

It is reported that Mr. Flavelle's handsome house in Queen's Park, Toronto, is likely to be purchased by the Ontario Government as a place of residence for the Lieutenant-Governors of the province. The house and its surroundings would seem to be well adapted to the purpose. If this change of location of the governor's residence be made, the City Council of Toronto should purchase for park purposes the present government house and grounds. The building, although somewhat out of date, appears to be in a fair state of preservation, and could be put to some public use, as for instance a museum. The grounds have been carefully kept, and contain some fine trees. They would give a pleasant breathing spot in the center of the city, the lack of which is becoming more acutely felt as population increases.

× × ×

Surgeon-Captain K. Tamura, of the Imperial Japanese Army, in a recent address to the military surgeons of the United States, called attention to the use of paper for windows in Japan, in place of glass. He referred to the fact that where no ventilation can take place through glass, the air passes through the paper quite freely. Moreover, the texture of the paper is such that, while admitting the air, it prevents in some degree the passage of germs through it. This point was determined by counting the number of colonies of bacteria developed on media inside and outside the house. It was thus found that 97 per cent. of the bacteria of the air were removed. The speaker summed up in the adroit Oriental way: "It is well known that a citizen of Paris inhales 7,500 bacteria germs in a day; one in Berlin, 5,000 of them. We Japanese, who live in air containing three times as many as Berlin and twice as many as Paris, inhale only 2,000 bacteria germs in a day, simply because we use paper for the windows of our homes."

"Punch" in the following lines depicts the sorrows of the professional man who is regarded as being either too young to be trusted or too old to be efficient:—

Two men there dwelt upon a time
Within a certain city.
Both were distinctly men of parts
Well versed in their respective arts.

To fell diseases of the kind
That everyone who can shuns
One of the pair had turned his mind,
The other's forte was mansions.
They were, as you'd no doubt expect,
A doctor and an architect.

The latter, when but twenty-nine,
Planned a Titanic building,
A house of wonderful design,
All marble, stone and gilding,
Said he: "My fortune's made, I wis,
Men can't resist a thing like this."

With eager hope his heart beat high,
He took his plans up boldly,
And thrust them in the public eye:
The Public viewed them coldly.
"Pray take that rubbish right away,
You're far too young for us," said they.

The doctor's was a novel treatment for consumption, but the public sternly rejected it also—

Apparently you quite forget
That you are barely thirty yet.

The years rolled on,

And then—the Public changed their mood!
Their hearts began to soften.
They felt the doctor's cures were good
(They'd had that feeling often).
They also chanced to recollect
The merits of the architect.

"Come plan us mansions, bring us pills."
Their cry no answer rouses.
No one alleviates their ills,
No one designs them houses.
Upon enquiry it appears
Each has been dead for several years.

On April 26th the feast day of St. Mark, the Count of Turin, representing the King of Italy, laid the corner stone of the New Campanile at Venice in the presence of 30,000 spectators.

HEAT RESISTANCE OF BUILDING MATERIALS.

At the recent meeting of the American Society of Mechanical Engineers a paper was presented by Mr. William Kent proposing the use of the reciprocals of the values of heat conductivity of substances in order to facilitate the comparison of different combinations of the substances. As stated in the report of the convention, he makes the coefficient of heat resistance or heat insulating power of a substance equal to unity divided by the number of British thermal units transmitted in one hour by a slab 1 square foot in area and 1 inch thick per degree Fahrenheit of difference of temperature between the two faces of the slab, both surfaces being exposed to still air. In this way the total resistance of a combination can be indicated by the addition of the several resistance coefficients. The author points out, however, that while the coefficient is thus a constant quantity for a given substance, it can only be so considered when the differences in temperature of the air on the two sides of the slab are small—say, less than 100 degrees Fahrenheit. When the temperature range is great, experiments on heat transmission indicate that the quantity of heat transmitted varies not directly as the difference in temperature but as the square of that difference.

The question of the effect of surface resistance when the surface is in contact with air or with another body, the author treats as follows: "Authorities on the subject of heat transmission generally agree that the resistance to the passage of heat through a plate consists of three separate resistances; viz., the resistances of the two surfaces and the resistance of the body of the plate, which latter is proportional to the thickness of the plate. It is probable also that the resistance of the surface differs with the nature of the body or medium with which it is in contact. Thus a very rough surface on a metal plate would be likely to transfer more heat to adjacent air than a smooth surface would, since it has a greater area in actual contact with the air, while two rough surfaces of metal touching each other would transmit from one to the other less heat than two smooth surfaces."

He has computed the figures for heat resistance of several insulating substances from the figures of conducting power given in a table published by Mr. John E. Starr, in a paper on "Insulation for Cold Storage," published in "Ice and Refrigeration" for November, 1901. Mr. Starr's figures are given in terms of the British thermal units transmitted per square foot of surface per day per degree of difference of temperature of the air adjacent to each surface. The author's figures, the coefficients of heat resistance, given in the second column of the accompanying table, are calculated by dividing Mr. Starr's figures by 24, to obtain the hourly rate, and then taking their reciprocals.

"Analyzing some of the results given in the last column of the table, we observe that, comparing Nos. 2 and 3, 1 inch added thickness of pitch increased the coefficient 0.74; comparing Nos. 4 and 5, 1½ inches of mineral wool increased the coefficient 1.11. If we assume that the 1 inch of mineral wool in No. 4 was equal in heat resistance to the additional 1½ inches added in No. 5, or 1.11 reciprocal units, and substract this from 5.22, we get 4.11 as the resistance of two ⅞-inch boards and two sheets of paper. This would indicate that one ⅞-inch board and one sheet of paper give nearly twice as much resistance as 1 inch of mineral wool. In like manner any number of deductions may be drawn from the table, and some of them will be rather questionable, such as the comparison of No. 15 and No. 16, showing that 1 inch additional sheet cork increased the resistance given by four sheets 6.67 reciprocal units, or one-third the total resistance of No. 15. This result is extraordinary, and indicates that there must have been considerable differences of conditions during the two tests."

HEAT CONDUCTING AND RESISTING VALUES OF BUILDING MATERIALS.

Brick Wall: Thickness.	Cond.	Res.	—Revised.— Res.	Cond.
4-in.	0.68	1.47	1.50	0.667
8-in.	0.46	2.17	2.30	0.435
12-in.	0.32	3.03	3.10	0.323
16-in.	0.26	3.85	3.90	0.256
20-in.	0.23	4.55	4.70	0.213
24-in.	0.20	5.00	5.50	0.182
28-in.	0.174	5.75	6.30	0.159
32-in.	0.15	6.67	7.10	0.141
36-in.	0.129	7.75	7.90	0.127
40-in.	0.115	8.70	8.70	0.115

Wooden beam construction, planked over or ceiled:	Cond.	Res.
As flooring	0.083	12.05
As ceiling	0.104	9.71
Fireproof construction, floored over:		
As flooring	0.124	8.06
As ceiling	0.145	6.90
Single window	1.030	0.97
Single skylight	1.118	0.89
Double window	0.518	1.93
Double skylight	0.621	1.61
Door	0.414	2.42

The author has also calculated the coefficients of heat resistance from the heat transmission figures of various building materials, as given by Mr. Alfred R. Wolff, based on German experiments. These values are reproduced in a table herewith, the first column giving the conductance, in British thermal units per hour, and the second, the reciprocals, or heat resistances. It will be noted that there is an irregularity of the differences in the value of the resistance for each increase of 4 inches in thickness of brick walls, which the author holds to indicate a difference in the conditions of the experiments. He finds the average difference is 0.80 and that the approximate formula for the resistance is 0.70+0.20 t, in which t is the thickness in inches. In the third and fourth columns are given the revised values of the resistance and conductance, respectively ascertained in accordance with his formula. —Engineering Record.

HEAT CONDUCTING AND RESISTING VALUES OF DIFFERENT INSULATING MATERIALS.

	Conductance.	Resistance.
1. ⅝-in. oak board, 1-in. lampblack, ⅞-in. pine board (ordinary family refrigerator)	5.7	4.21
2. ⅞-in. board, 1-in. pitch, ⅞-in. board	4.89	4.91
3. ⅞-in. board, 2-in. pitch, ⅞-in. board	4.25	5.65
4. ⅞-in. board, paper, 1-in. mineral wool, paper, ⅞-in. board	4.6	5.22
5. ⅞-in. board, paper, 2½-in. mineral wool, paper, ⅞-in. board	3.62	6.63
6. ⅞-in. board, paper, 2½-in. calcined pumice, ⅞-in. board	3.38	7.10

16. Same, with 5-in. sheet cork	0.90	26.67
17. Same, with 4-in. granulated cork	1.70	14.12
18. Same, with 1-in. sheet cork	3.30	7.27
19. Four double ⅞-in. boards (8 boards), with paper bet. three 8-in. air spaces	2.70	8 89
20. Four ⅞-in. boards, with three quilts of ¼-in. hair bet. papers separating boards	2.52	9.52
21. ⅞-in. board, 6-in. patented silicated strawboard, finished inside with thin cement	2.48	9.68

NORTHWEST LETTER.

WINNIPEG, MAY 11, 1903

The open spring this year has been most favorable for building of all descriptions and has allowed the work to get under way considerably earlier than last year. Excavations, large and small, can be seen everywhere from the centre of the city to the outlying districts in the suburbs, and everything is activity in the building line. Some of the foundations of the smaller work have already approached the ground level and where the building is frame many are well covered in.

Before taking up the new work it would be in order to mention the two or three large works that were started last year and are now at the point of completion.

The Strathcona Apartment Block is the most noteworthy in this list. It is a building that will be welcomed by the great class who live in "Rooms". The population of Winnipeg has increased so during the past twelve months that house accomodation has become a most serious question and one that is already having an adverse effect on incoming residents and resulting in temporary detriment to the city. The opening of the Strathcona will therefore be heralded with delight by a host who at the present moment may be living more or less like sardines in a box. It will relieve the pressure in this direction to some small extent, but will not in any way settle the important question of housing. Winnipeg is a most favorable place for apartment buildings as the population for the most part is a very transient one and buildings of this description are ensured financially as being a most paying investment. To describe the Strathcona building is not a very serious undertaking as everything inside and outside has been carried out in the most simple manner. The building is constructed of the common gray brick, it is four stories in height with a high basement. On plan it is a square with a large centre court. From this court is arranged an entrance in each corner to the building proper which divides the whole into four separate parts. On the ground floor, first floor, and second floor each part is divided into two suites of from six to eight rooms with bath room accommodation for each suite. The finish of the main portion on ground and first floors is in oak and on the second floor maple. The top floor is reserved for bachelors' quarters and divided into separate and double rooms. What appears to be an omission especially in a building of this description is the lack of a passenger elevator, but in the planning of the work it may have been found undesirable. The use of metal ceilings throughout is a feature that strikes one as being most objectionable, and one that would not be tolerated in a very ordinary residence.

St. Mary's Academy is another building that was started last year and will be completed in the course of a couple of months. This building has apparently been designed with the object of getting the most accommodation for the least amount of money. Externally, the work is so extremely simple and the lines so hard that the general effect is most disappointing and a crudity in design pervades the whole work. Inside everything has of necessity been kept as simple as possible and even the Chapel, which in these Institutions is generally made a special feature is, from all appearances, being treated in keeping with the rest of the work. The tenders for this building were originally much in excess of the anticipated cost and consequently everything had to be reduced to the simplest form.

St. Stephen's Church, although not yet complete, will from present indications be one of the most interesting Churches in the City. It is faced with Tyndall stone thoughout and makes a very substantial looking block. The Sunday School forms part of the same building and the uninitiated on entering is much surprised at the small area of the body of the church. This of course may not have the same effect when the seats, etc., are arranged in position. The Church will be open for service in the course of a few weeks.

Of the new work already begun the Bank of British North America is the largest. This is to be a four-storey building, the ground floor space reserved for the Banking room and the upper floors as Offices. The front will be of Bedford stone with pilasters, cornice, pediment, etc., and when completed will rank among Winnipeg's finest buildings.

The Steele Apartment Block which has already part of the foundations in is to be a brick building of simple character and has been designed on strictly utilitarian lines.

Of the Warehouses in course of construction, and there is a great number, the Stobart building is the largest. The foundation walls are now being rapidly pushed.

The postponing of the C. P. R. improvements indefinitely, is most regrettable, and it is an action that touches the general welfare of the City. The suspension of operations on this work will affect the North end most directly and will cause building in this district to be put off until arrangements have been finally decided upon. The cause of the delay is due to a question of legal claims that will be instituted against the City by property owners in the vicinity of the proposed subway. As the amount of these expected claims is an unknown quantity and might with all reasonableness reach an extremely high figure, it appears to be a most important factor in the negotiations as to who shall be liable for all such claims that may be filed. As these improvements must be proceeded with in the near future it is to be hoped that a satisfactory understanding can be arrived at immediately and work begun.

A deputation from the Winnipeg Board of Trade left here some days ago for the purpose of interviewieg the Dominion Government on behalf of merchants and contractors of this city regarding the tardiness of the C. P. R. in their efforts to facilitate the shipping of goods and materials into the city. This subject cannot be placed before the Government in too trenchant terms as the prosperity of the West and especially of Winnipeg is dependent upon the speedy supply of materials from outside. If the C. P. R. officials are not at fault in this on the plea of increased traffic throughout the country the Government should take steps to devise some scheme that will insure the necessary movement of goods in this district. Building has already been stopped for several days on account of the lack of stone. The stone is quarried and in some cases loaded on the cars but the delay in the transporation of same to Winnipeg has caused valuable time to be lost by waiting.

The real estate boom here is now at its meridian, and city property is, from what I can learn, at a price it will not exceed for some time to come. Outlying districts have been surveyed and laid out, and a sufficient area has been plotted to satisfy the demands of an increasing population for the next decade. Prices asked for local farm lands are so high as to be almost probibitive to buy even as house property. Winnipeg is flooded with a myriad of real estate agents. Every other office is occupied by a real estate man or has desk room for one, and each has his alluring list of lands for sale to proffer the would be purchaser. Practically half of Winnipeg is for sale by this horde of ephemeral land agents, who foist up the price at each transaction and through whom property in some cases attains a remarkably fictitious value.

I regret that I am not able to forward you for illustration the plans of the Carnegie public library. Two sets of drawings have already been figured on, but the cost in each case is much above the stipulated cost. The plans of the third successful competitor are now being tendered on, and until the figures are received it is impossible to say what will be the next steps taken to proceed with the work of building a library.

W. PERCY OVER.

The cement, which was used in the decoration of the baptistry at Florence, was composed of wax, lime and resin. It was very good for its purpose, for it kept sufficiently moist for five to eight hours, and could during that time be worked as wax, and then it became as hard as stone and did not shrink.—Sir W.B. Richmond.

JOTTINGS FROM AN ARCHITECT'S NOTEBOOK.

Plinths, string courses, cappings, and other running members worked in stone should be in as long lengths as possible to avoid a multiplicity of joints, which will assuredly take wet in when the pointing fails. Internal and external angles to all such dressings are worked solid, and not mitre jointed. When any horizontal member abuts against a vertical wall, the member should be worked solid on a block which is to be built into and form part of the wall surface. Projecting members in soft stone are sometimes weathered with 5-lb. sheet lead in short lengths, dressed closely down on the stone; built at least 2in. into the horizontal joints along the inner edge, and projecting from ¼in. to ¾in. over the most prominent member so protected. In using lead to protect stonework, it should be left ree along one edge and end, for this material expands and contracts very perceptibly under the changes of temperature to which it is exposed in this climate; for the same reason it should be used in as short and narrow pieces as possible. Portland cement and lime putty are ideal materials for pointing the joints of stonework, assuming that the latter does dot expand and contract when subjected to extremes of heat and cold. But as it is a well-ascertained fact that stone, like metal, increases in bulk with an increase of temperature, it follows that any material used for stopping a joint in stonework must be stretched and compressed alternately, which action will ultimately destroy the jointing material as a watertight seal where it is inelastic. Hence a perfect material for jointing stonework should be possessed of some amount of elasticity—say, like asphalt. An open joint ½in. wide will take in less water than one 1-16in. wide, owing to the operation of a force called "capillarity." It is well known that if a piece of sugar is held in contact with water at one extremity, the fluid will rapidly pass into and moisten the whole lump. The same action may be observed by using a piece of ordinary mortar which has been thoroughly dried, especially if made with burnt ballast, or a piece of oven-dried sandy building brick. Where a stone or brick wall is damp on the inside, the bricks, stones, and mortar joints being perfect, the damp passes through the substance of these materials by capillary action. In a joint or crack where the adjoining surfaces are planes or irregular, and in contact at one or more edges or points, rain water will be taken up and held, or passed on to the inside by pressure from the outside. This peculiar action, due to what is sometimes called molecular attraction, another name apparently for capillarity, is observable in a closely slated roof, where a quantity of water is held after rain between the bed surface of one slate and the backs of those immediately underlying it. An open joint, where the surfaces are nowhere in contact, will be more weather proof than a close broken joint where the fissure is a mere crack. A window sill broken between the joints is generally the cause of a wet window back, and a sill damaged in this way should be wholly removed or repaired by cutting away the edges, and inserting a new block from 4 in. to 6 in. wide to the full width and depth of the sill. To attempt any repair of the cracked stonework by pointing with mortar, cement, or glazing putty is worse than useless. In this connection it is a question, when a wall is covered by a deep projecting cornice, whether it would not be advisable to set the stones on a sheet of lead, so that when the joints break, any water entering them may be caught and prevented from passing down through the wall. Sheet lead used in this way would perform the same office as a lead safe to a bath or w. c. apparatus; there is a difficulty, however, in the use of lead, especially in connection with lime or cement points, for the mortar may be converted into the carbonate (PbO, CO_2), in which case it would be quite useless. A stone gutter lying between the nave and aisle roofs of a sixteenth-century church was hollowed out 10 in. wide and 6 in. deep, the stones being from 16 in. to 18 in. long; the hollow was lined with cast sheet lead, which weighed orginally about 12 lb. to the foot; this lead lining leaked badly, and when removed it was found that more than half its thickness was converted into lead carbonate (white lead). Whether this was due to the presence of lime in the joints of the stonework or to rain-water, which was found between the lead and the stone gutter, it was not easy to determine, but the conversion of the metallic lead into the carbonate was no doubt commenced by pure rain water which in some way found an entrance to the joint between the lead and stonework. It is well known that clean metallic lead will, if dipped in rainwater exposed to the air, form a scale of what is probably lead hydrate, or hydrate and carbonate, a compound similar to ordinary pure commercial white lead. From the foregoing remarks it will be seen that the use of lead as a protective covering for structures may be advantageous in many cases, but it must be cautiously dealt with, allowing for free contraction and expansion, keeping it from contact with other metals in presence of moisture, and not exposing either surface to stagnant water in bulk, or merely a film which may be constantly evaporated and renewed. In many buildings it is a very common plan to let wrought-iron balusters directly into the ends of stone steps and landings. Where these are under cover, the oxidation of the ironwork does not take place so rapidly as when they are exposed; but all the same, in course of time, from the water used in washing the steps, and hygrometric moisture, oxidation sets in, and the iron rails burst the ends off the stone steps. It therefore follows that iron stair balusters should not be leaded into stone steps, nor is there any reason why they should be, for the flange of a rolled-steel string fixed under the outer ends of the steps and landings will not only carry and strengthen the staircase, but the walls may be drilled to take iron brackets, which, in turn, will hold the iron balusters. By adopting this plan all the stonework rests in the walls at one end, and on steel girders on the other. A thrust against the balusters and rail does not try the cohesive strength of the stone steps, but is transmitted to the steel ring, and both steps and landings are supported in the best possible way to carry their own weight and the weight of any number of people that may suddenly be brought on them, and this latter is an important consideration in a public building. Solid steps set in masonry have usually a lap of about 1 in.—that is, the tread of one step underlies the riser of the next 1 in. Steps having the soffits or undersides exposed are rebated or splayed where the riser of one step rests on the step underlying it. Steps supported on a wall at one end are usually in not less than 4½ in. The underside of each step may be horizontal, or splayed to form what is known as a "spandrel" step. In the first case the section of the step is a rectangle, in the latter a triangle.

Narrow staircases in church towers are worked circular in plan, a piece of the newel being worked in the end of each step; this newel is usually from 5in. to 6in. in diameter, and the whole staircase from 5ft. to 6ft. The steps may be rectangular in section or triangular. In such a staircase all the steps are worked to the same mould or template, and they are built in as the walls are raised. There is no ironwork needed in the construction of the stairs, as the steps are supported in the wall at one end, and on the newel at the other. The steps in eacb completed circle of a geometrical staircase should rise not less than 8oin. which would give 6ft. headroom, and allow 8in. for the thickness of a step.—Building News.

WIRE-GLASS WINDOWS.

The subject for which I shall have the honour of asking your consideration will be "Wire-glass, the Fire Retardant," a building material which tends to reduce to the minimum the hazard of conflagration, and conduces to the elimination of some risks attending the lives of us humble fire-fighters. The range of possibilities in fire protection is too wide to speak of here, if I am to be favoured with your attention, and only a small portion of it can be engaged in during the short session. I shall endeavor to advance that which I believe to be the most important factor in the protection of buildings against conflagration, and I shall be amply rewarded if I enkindle in your minds an inclination to seek more information upon the subject than I am enabled to communicate.

It is manifest to all thoughtful minds that the phenomenal development of the real estate values in our cities has made the tall building a necessity, and this necessity has brought with it the need of adopting in building construction barriers to conflagration, and there are to-day buildings capable of enduring without structural injury fierce, long continued interior and exterior flames and the application of cold water upon their heated surfaces. Structurally a building of this class is admirable—the foundations are secure, the walls and roof fireproof, but openings in walls and roof are necessary to render it habitable. Obviously the vulnerable parts of a building are the openings in the walls and roof—its doors, windows and skylights. To these openings the spread of flame is almost wholly attributable. This has been the history of so many destructive conflagrations that experts have long agreed that no structure in a closely built city can be considered even approximately secure against fire so long as it is provided with only ordinary windows, skylights and doors. My experience and observation have been such as justify this opinion, and I have most strenuously maintained that the quantity of wood contained in what I have termed "a structurally fireproof building," taking into consideration also the furniture and fittings, would, in the event of fire, endanger the property and the lives contained within it.

Shutters of iron or of metal-covered wood may protect windows if they are carefully closed, but in practice such shutters fall short of the purpose for which they were intended. When the crisis comes the shutter is frequently found open. Under the most favourable conditions an iron shutter at a fire is not the thing that the firemen want to come in contact with. Its rusty fastenings and blistering sides are objectionable, to say the least, and its reach, when it swings open, is liable to knock a man off the ladder. This is a risk to which the fire-fighter should not be subjected. There is no braver, manlier or more faithful set of men in the public service or out of it than the brave lads enrolled in our fire departments. I know of whom I speak, and I am well acquainted with the chances they take. They are ready to fight with death every day. Every year sees them saving life heroically or dying in their duty. Their work is as trying, difficult and dangerous as there is in the world. Yet they are not safeguarded. I know what ready fellows they are, and I feel that all known means of protection should be adopted to render their calling less hazardous.

Wire-glass is, in my opinion, the fire-stop for window and skylight openings—wire-glass set in metal frames. It supplies the requisite light and ventilation as well as protection against fire; its installation obviates the necessity of the cumbersome and unsightly hinged shutters and the projecting lugs and adjusters which support and secure them. It affords protection regardless of the janitor's neglect, because the thought of fire is not necessarily present in the mind of the tenant to induce him to close the window-sash, and when closed it prevents the ingress, egress or communication of flame. It enables the fire chief to size the situation and direct his men intelligently. The location and volume of the blaze are immediately disclosed, and if the conditions warrant it the fireman can effect an opening for the stream with his fire-axe.

Hard conditions, great risks and the sacrifice of large property and many lives are preliminary to the establishment of standards, and by such means wire-glass has come to be recognized as standard, and the degree of honour which is its legitimate due should be generally recognized.

Succinctly stated, wire-glass has yielded two fixed values as its contribution to fireproof building construction:—

It retards fire without hiding it—permits the blaze to declare itself.

It can be cracked, but it cannot be scattered. If fractured it retains its place.

Now we have to remember what we cannot forget, and we are mindful, thereof, of experiences which enable us to fully appreciate the value first stated. Of the many embarrassments to which the fire-fighter is subject, that which prevents fire from disclosing its location in its incipient stage is the most serious. Within the congested districts of our great cities our organizations are such as enable us to reach the scene of action and have our nozzles in hand within two or three minutes of the alarm, and if we could immediately get at the fire we would, in most cases have little difficulty in confining the blaze within the limits of the apartment in which it originated.

Modern science has equipped our departments with devices necessary to combat fire, the most contagious, virulent and disastrous of all perils to which buildings are subjected, and modern science has devised the means by which fire can be confined within the walls of buildings without rendering the same, inaccessible

*A paper by Edward F. Croker, chief of Fire Department, city of New York, read at the thirtieth annual convention of the International Association of Fire Engineers, New York.

to us, but the adoption of the means available is not general, and upon arriving at a fire we are frequently confronted with tin-covered and iron-clad shutters which obstruct our vision and our efforts to locate and conquer a blaze which becomes a conflagration, because of the precious moments lost in concentrating our energies upon the seat of trouble.

This condition has long been a serious menace in all cities, and it is now intolerable because the installation of wire-glass presents no technical difficulties. It is of acknowledged efficiency and no less economical than effective. It has withstood the severest tests, and its cost is well within the means of all building owners. The insurance companies give preferred rates when it is installed, and thus practically invest in it. Their scheme is to reduce hazards and in the belief that wire-glass effectually accomplishes this they induce its adoption by substantial endorsement. Its ability to abate horrors and loss which attend conflagrations in cities is ample justification of the reasonable laws providing for its adoption, and an exigent public duty is presented to building inspectors to prevent these laws being nullified by official inertia.

There is a region paved with good intentions, and many easy-going owners of buildings contribute to this paving fund by deferring the adoption of known means of protection and at the same time create occasion for regret from heavy financial loss and probable loss of life. I want to see the obligation placed upon owners of buildings to prevent such losses by the means which will effectually render fire non-communicative, and I think I have specified the means. The significance and overwhelming argument in favor of wire-glass as a fire-stop is the fact that when fractured it retains its place and continues to retard draught and its attending flames.

Doubtless many of the chiefs present have had occasion to recognize the efficiency of wire-glass as a fire-stop, and, of the many, Chief Musham's experience is especially worthy of reference. The fire which destroyed the Armour Lard Refinery, Union Stock Yards, Chicago, on the night of May 16, threatened for a time the entire district. Chief Musham was present, and he has stated that the wire-glass in the windows of the several walls prevented any communication through them and demonstrated the ability of wire-glass to prevent the spread of flame. The building destroyed was of recent construction, 100 feet by 400 feet, five storeys in height, and sub-divided into four sections by fire-walls, two of which were completely destroyed.

The quantity and nature of the material in combustion—refined lard—resulted in the hottest kind of a fire, and its intensity and duration are hardly comprehensible. The chief tells me that the flames reached to a height of 150 feet above the roof, and the combustion was so perfect that scarcely any sparks were observed.

I am quoting Chief Musham because I think perhaps his observation of wire-glass in this instance was under a better condition than can be conceived for an actual service-test of wire-glass. The entire interior of the building was of inflammable construction, made more so by being saturated with lard, and its five great floors were loaded with tons of this highly combustible product. Tanks containing thousands of gallons of rendering were exploded and their contents dashed against the walls and windows, and the intensity of the heat was so great that the walls holding the frames and sash which accommodated the glass crumbled, but until they fell the wire-glass retained its place.

This fire establishes conclusive proof of the efficiency of wire-glass as a fire-retardant and its staying qualities, and for the purpose of illustrating my subject I have considered it preferable to my own experience.

ARCHITECTS' ACCOUNTS.

General practitioners in medicine usually decline to give particulars of their charges, or even to state the number of times they have visited a patient. An Architect's account say the Builders Reporter, is presumed to offer less difficulty to those who wish to examine it, for it is taken to be at the most 5 per cent. on the outlay. When it is found that an account will not work out at that rate there is discontent. An example of the difficulty which people find in recognising any other basis was presented at some late meetings of the Guardians of Newton Union in Devonshire. New works were to be carried out in connection with the workhouse. For that purpose it was necessary to make plans of existing buildings, which were to be removed in order to furnish part of the site. Mr. Seger, the architect for that survey, claimed seven guineas. Some of the Guardians, including the chairman, declined to approve of the account, on the ground that the 5 per cent. commission was to include everything. The chairman repeatedly asserted that there should be only one charge, 5 per cent., and that he had never heard before of payment for plans of sites. However, the good sense of the majority prevailed, and the charge was admitted. It is hard that gentlemen holding administrative offices know so little of architectural practice as to imagine it is of so simple a nature that one charge can cover the vast variety of incidental work which may arise, and which the architect can no more be compelled to execute than to discharge the functions of a lawyer in connection with the building.

NOTES.

The death is announced of Prof. T. Roger Smith, for many years Professor of Architecture and Building Construction at University College, London. The late Prof. Smith was twice elected President of the London Architectural Association. He was also the author of a valuable work on acoustics.

France is about to start schools of architecture in the towns of Lille, Rouen, Nancy, Lyons, Bordeaux, Marseilles, and Toulouse. The course of study will last seven years, diplomas will be given, and the professors, from twelve to fourteen in number, according to the schools, will be elected by the Conseil Superieur des Beaux-Arts.

At a recent architectural conference in England, the ethics of the profession were made the subject of a paper and a discussion, but nothing practical followed. What is necessary in the interests of the profession says the Building News, is that fundamental points or questions should be settled once for all; such questions, for instance, as touting, interference with brother architects' work, calling on other architects' clients, inclosing testimonials to clients and members of committees, to competition promotors, accepting any work that would compromise any professional brother's position, giving evidence in courts of law prejudicial to architects, &c. These and other matters, if once decided upon in a representative conference of the profession, and the conclusions issued in a code to every practising architect, might be the means of uniting the profession; but it may be asked whether architects can ever agree on any subject of this nature?

ARCHITECTURAL EDUCATION IN GERMANY.

The usual requirements for admission to a German technical high school is a certificate showing that the student has completed his course in a "gymnasium" and has passed the graduating examination. This admits the holder to any university in the country. Foreigners are admitted if they can show that they have pursued a course of study in their own country approximately equivalent to that of a "gymnasium," but they are not allowed to take the Government examinations.

Anyone who wishes to take up some course or separate subject at the Hochschule, but is not able to fulfil the requirements for admission as a student, may be admitted as a Hospitant, or guest, simply attending the lectures, but not receiving any diploma at the end of his course.

The course occupies four years, and leads, for those who wish to enter the Government service, to the title of Baufuhrer, or "Director of Building," and, since October, 1899, also to the degree of "Doctor of Engineering." Those who do not enter the service of the Government, but have successfully completed their four years' course, receive a diploma to that effect.

The first two years are devoted almost entirely to theoretical subjects, or, at any rate, to subjects which do not pertain directly to architecture, but which it is well for an architect to know something about.

The subjects taught during each term are as follows:—

Winter Term: First Year.—This the first term of the first year (from the middle of October to the middle of April):—

Differential and Integral Calculus.—(5 hours' lecture: 1 hour's recitation.)

Analytical Geometry.—(2 hours' lecture.)

Descriptive Geometry.—(3 hours' lecture: 6 hours' drawing.)

Mechanics.—(3½ hours' lecture: ½ hours, recitation.)

Construction (Masonry and Carpentry).—(3 hours' lecture: 4 hours drawing.)

Architectural Drawing.—(3 hours.) Instruction here consists of copying architectural subjects in different mediums—pencil, charcoal, pen and brush, so as to become familiar with the handling of different materials.

Elements of Mineralogy.—(2 hours' lecture: 1 hour's recitation.)

Experimental Physics.—Mechanics, heat, acoustics and optics. (4 hours' lecture.)

The Summer Term is shorter than the first, lasting from the middle of April to the end of July. During this time, in the first year, the following curriculum is prescribed:—

Differential and Integral Calculus.—(3 hours' lecture: 1 hours' recitation.)

Descriptive Geometry.—(3 hours' lecture: 6 hours' drawing.)

Mechanics.—(7 hours' lecture: 1 hours' recitation.

Construction.—Foundations; walls and supports of wood, stone and iron; stairs and elevators of stone, wood and iron. (2 hours' lecture: 4 hours' drawing.)

Architectural Drawing.—(6 hours.) Devoted to the same subjects as during the winter term.

Elements of Geology.—(4 hours' lecture.)

Elements of Chemistry.—(6 hours' lecture.)

There is no summer work prescribed, and, therefore, none done. The drawing rooms are left open for the convenience of the students who have back work to make up. There are usually plenty of them.

During the Easter and Whitsuntide vacations, excursions (headed by some of the professors) are undertaken, places of special architectural interest being selected. These expeditions usually last about ten days.

The winter's work in the second year consists of 51 hours a week: 26 devoted to lectures and the other 25 to recitations and drawing. During this year the student gets to know a little more about architecture itself, but most of the subjects are still very theoretical and rather auxiliaries of architecture than architecture itself.

Here is the list of subjects taught during seccond year.

Mechanics of Elasticity.—(5 hours' lecture; 1 hour's recitation.)

Graphical Statics.—(1 hour's lecture.)

Study of the Forms and History of Ancient Architecture.—(3 hours' lecture: 6 hours' drawing.) This course also includes a careful and detailed study of the Orders, the copying of the best examples of ancient architecture, and one large and carefully executed design in either the Greek or Roman style.

Ancient Ornament.—(2 hours' lecture: 2 hours' drawing.

History of Ancient Art.—(3 hours' lecture.)

Construction.—(2 hours' lecture: 4 hours' drawing.

Architectural Building.—(1 hour's lecture.)

Modelling.—(4 hours).

Figure-Drawing from Casts.—(6 hours.)

Elements of Civil Engineering.—(3 hours' lecture.)

Elements of Surveying.—(2 hours' lecture.)

Technology of Building.—(3 hours' lecture.) By this is meant instruction in the manufacture of bricks, plate-glass, mining, casting of metals, and so on, the lecture being illustrated by the inspection of factories and plants in operation.

The summer term has 49 hours a week, of which 25 are taken up by lectures and 24 by exercises. The subjects are almost identical with those of the winter session. The lectures on the "History of Ancient Architecture" are replaced by others on "Romanesque Architecture"; likewise those on "Ancient Art" by others on the "Art of the Middle Ages." However, the drawing and designing of the course in ancient architecture is kept up. With the third year the real architectural work begins. All the preparatory work is accomplished, and now the students are first acquainted with the various styles of architecture and with the principles of design.

A few large problems are very carefully worked out, with a couple of smaller ones interspersed. The styles in which these designs are to be carried out are usually prescribed, the idea being to make the student thoroughly familiar with the forms and ornaments of all the historic styles. Having thus become conversant with the historical development of each style, and having tested its applicability to practical design, he may then accept, modify or ignore them in his later work, as he may see fit.

This system of studying each style separately from the design point of view is carried so far in Germany that, for their Gothic and Romanesque year, many students will visit a Hochschule where some professor who has made these styles his specialty has charge of the course, and for their Renaissance year will go to some other Hochschule where a master of that style holds his lectures.

The programme for the winter of the third year is as follows:

PLANNING OF DWELLINGS AND PUBLIC BUILDINGS.—(2 hours lecture.)

HISTORY OF RENAISSANCE ARCHITECTURE.—(2 hours lecture.)

DESIGNING AND DETAILING OF DWELLINGS.—(1 hours lecture; 5 hours drawing). Besides instruction in the designing of dwellings, this course includes the making of working drawings and full-sized details.

MEDIÆVAL ORNAMENT.—(2 hours' lecture: 2 hours' drawing.)

DESIGNING IN THE EARLY CHRISTIAN AND ROMANESQUE STYLES.—(3 hours' drawing.) This includes sketching and careful working-out of a problem from a given programme, also the making of perspectives from drawings and also from nature.

HISTORY OF GOTHIC ARCHITECTURE.—(3 hours' lecture.)

HISTORY OF RENAISSANCE AND MODERN ART.—(3 hours' lecture.)

ARRANGEMENT AND PLANNING OF BUILDINGS. — (2 hours' lecture: 3 hours' drawing.) This course considers the treatment of buildings of every class.

LANDSCAPE-DRAWING AND WATER-COLOURING. — (2 hours' drawing.)

LIFE CLASS.—(6 hours' drawing)

The only difference between the winter and summer terms is that during the winter the course of lectures on machinery takes the place of the 2 hours a week devoted to landscape-drawing and water-colouring.

Of the 35 hours a week of the fourth year's winter term 24 are devoted to design, so that the absence of design from the first two years of the course is made good to a certain extent in the last year. During this last year the following subjects are taken up:—

RENAISSANCE DESIGN.—(6 hours' drawing.)

MONUMENTAL BUILDINGS AND LAVING-OUT OF CITIES.—(1 hours' lecture: 4 hours' drawing.) In connection with this course a series of 5-hour sketch-problems is given out, subjected later to a comparative criticism.

HISTORY OF THE USEFUL AND DECORATIVE ARTS.—(2 hours' lecture.)

INTERIORS WITH COLOURED DECORATIONS.—(5 hours' drawing.)

DESIGNING OF PUBLIC BUILDINGS IN THE STYLES OF THE MIDDLE AGES.—(2 hours' lecture: 9 hours' drawing.)

LIGHTING, HEATING AND VENTILATION.—(3 hours' lecture.)

ELEMENTS OF ENGINE-BUILDING.—(3 hours' lecture.)

The student who has successfully completed this course is deemed ripe to begin his existence as an architect. To those who have passed the Government examinations, position and a future are assured. This brings one to the subject of examinations.

At the end of every term each student may take an examination in any subject in which he has registered. This is, however, entirely optional on the part of the students, and, as a rule, but few avail themselves of this privilege. For the students of architecture are no more prone than others to go to the trouble of preparing for an examination which is not obligatory and is not required for graduation. The real object of these examinations is to give those students who, for some reason, do not intend to take the regular prescribed examinations a chance to find out how much or how little they have learned during the term.

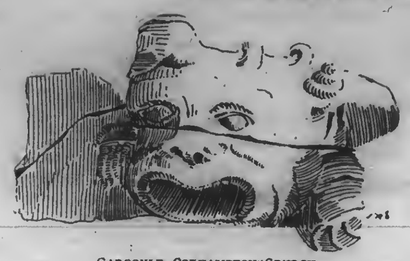
There are two distinct types of examinations, one the Staalsprufung, or Government examination, the other the Diplomprufung, or diploma examination. The subjects required are the same in both cases. The only difference between the two, as far as the examination itself is concerned, is that the one is held by an Examination Board appointed directly by the German Government, whereas the other is conducted by officers of the school. Whoever successfully passes the Government examination receives the title of Regierungs-baufuhrer, or "Government Director of Building," and can enter the Government service if he so wishes. As we have already seen, only those who have completed a nine years' course at a German gymnasium are entitled to take this examination. Naturally, all students who have fulfilled these requirements take the Government examination in preference to the other, if only for the sake of the title, even though they do not intend to enter the Government service. There are many of this class. For although the Government service offers a sure berth and a regular salary, and also a pension after retirement, the conditions are so unfavourable that but few are willing to undertake it.

The young Baufuhrer has to give the first year or year and a half of his services to the Government without receiving any remuneration whatever. Before becoming a Baumeister, the next rung of the Government ladder, an exceedingly difficult examination requiring a full year of preparation must be passed. The Baumeister receives a fairly good salary, and most who have reached this stage stick there till they are middle-aged men, when, if they are fortunate, they may be appointed Baurath. In spite of the fact that these unfavorable conditions have led to a great scarcity of Government architects, the German Government has till now refused to improve them, but will surely be forced to do so. Under existing circumstances, only those men who have not enough confidence in their own ability to hope for success in their battle with the world are apt to enter the Government service. This naturally leads to a deterioration of the work done for the Government and a change is sure to be made, and made soon.

The student who passes the other examination receives a diploma from the Hochschule to that effect. The purpose of these diplomas is to give the students who cannot take the Government examination an opportunity of proving that they have successfully completed the entire course in their special subject. The same subjects are required for the Government and diploma examinations.

A thesis design, for which two months are allowed, is required. Admission to the Final Examination depends on the acceptance or rejection of this design.

Most of these examinations are oral. In the mathematical subjects they are partly written, partly oral. Naturally, drawing plays a large part in them. The examination in each subject lasts either an hour or an hour and a half, and, usually, three students are examined at a time.



GARGOYLE, CORHAMPTON CHURCH.

PROPOSED TECHNICAL INSTITUTE FOR MONTREAL.

The Committee representing the educational institutions and various public bodies in Montreal appointed to enquire into the question of the establishment of a Technical Institute in that city has presented the following report:—

"Your Committee is of opinion that the time is ripe for the establishment in this city of a technical institute suitable to the needs of the people. Should the citizens be in earnest in the desire, which has been so frequently and widely expressed, for such provision as will enable the boys and girls, the young men and women, to have better facilities for securing an education along the lines indicated in the report submitted by the delegation which visited the States, your Committee has no hesitation in saying that such an institute could be erected, equipped and placed in working order, in a satisfactory manner without delay.

Such an institute should be built in sections, commencing with the departments for which there seems to be the most pressing need. In every case these sections should be built with a view of future extension. The work could then proceed so as to allow of expansion as funds become available.

Sec. 1. It is further recommended: That courses of instruction in mathematics, English, French, science, the elementary principles of mechanical and electrical engineering, and in mechanical drawing, etc., be commenced in September next.

Sec. 2. That as soon as practicable, steps be taken for the erection of a section devoted especially to technology, and of the general dimensions and character indicated in the accompanying rough sketches.

On the ground floor is located offices and a machine shop.

On the second floor is placed the wood-working shop, together with a suitable lecture room and other offices.

The third floor is sub-divided into laboratories for wood-carving, art metal work, etc.

The whole of the fourth floor is set aside for descriptive geometry and mechanical drawing.

In recommending a building of this type, for immediate erection your Committee is influenced by the fact that there is evidently a very wide demand for such courses of instruction as would then be possible. As a proof of this it may be stated that considerably more than $100,000 per annum is being paid to correspondence schools in the United States by mechanics in this city desirous of obtaining instruction in the elements of mechanical engineering, etc.

Sec. 3. The second main section of the institute, which your Committee considers of great importance, should be devoted to applied art and design and to domestic science. These branches could be provided for in a building of the same general dimensions as that devoted to technology.

The fourth floor of such building might be devoted to the domestic science department, including biology, the study of foods, cooking, dressmaking, millinery, needlework, art needlework and embroidery, together with the necessary lecture rooms.

On the third floor provision may be made for the freehand drawing, drawing from the model, modelling in clay, and drawing from life.

On the second floor provision may be made for applied art and design in its various branches, including drawing from the life, painting in water colors and in oils, the design and painting of fabrics, wall papers, book engravings, posters, etc., and all different kinds of art work.

On the ground floor are placed the administrative offices of the whole building, also a museum, library, etc.

Your Committee is of opinion that there is an increasing demand for instruction in art and design, and also in domestic science. This is proven by the fact that large numbers of young people of Montreal are obliged to leave the city to obtain the instruction in question, while the demand for classes in domestic science is far greater than can be met by present arrangements.

Again, as has been already pointed out, the great success of the Philadelphia Textile school has been largely due to the fact that it has been worked in connection with a school of art and applied design. Your Committee, therefore, considers that it is of the highest importance to all interested in textile industries, to note that in the proposed department of applied design they will have the fundamental provision which is so necessary to the complete success of textile work. Your Committee would suggest that the textile department be erected, with a school of art and applied design, as shown on sketch. The general equipment and arrangement of these must be decided upon by authorities on textile work, of whom we have many able expositors on our Committees.

TRADE DEPARTMENTS.

Sec. 4. Next in order, and, in the opinion of your Committee, of great importance, is the proper establishment of suitable departments for the various trades, carpentry, plumbing, bricklaying, stone cutting, galvanized iron work, blacksmithing, fresco work, house painting, wiring, etc. There is undoubtedly a very large demand for courses of instruction in these departments, and this work should be commenced as soon as possible.

Your Committee is of opinion that steps should be immediately taken to provide, by correspondence, such courses of instruction as may meet the demand of those in this country who are too far from the city to take advantage of the special courses to be provided in the proposed technical institute.

Your Committee recommends that other departments be added from time to time as the demand may justify.

Your Committee would conclude this report by expressing the opinion that all students of the Institute should be required to pay fees. It is recommended that the fees for the evening classes be much less than for the day classes, and that the charges for the former be moderate. All the investigations of the Committee go to show that the best results have been obtained in those Institutes where fees are levied, as the students themselves prefer the feeling of independence which they naturally possess with the knowledge that they are paying for the instruction they obtain."

FOLDING.

We have the folding bed,
The folding bath-tub, too,
And folding chairs, its said,
Are nothing very new.

Some hat-racks shut up tight
In most ingenious way;
A couch for use by night,
A Sofa by day.

The folding table's found
Wherever man may roam,
And folding doors abound
In every modern home.

But one thing now we need,
And soon we will have that,
For in brief time, indeed,
There'll be a folding flat.

The Department of Buildings at New York has been conducting a series of tests to discover leakage of illuminating gas in many of the prominent theatres and hotels and Dr. Lloyd, of that city, has been making similar tests in dwelling-houses. The latter experiments had reference to the condition of certain patients who exhibited symptoms bearing close resemblance to those noted in typhoid or malaria, without manifesting the usual stigma of those diseases. As a result Dr. Lloyd found present in the rooms of these patients sufficient quantities of carbon monoxide, one of the constituents of illuminating gas and of sewer gas, to account for the symptoms noted. The device used to ascertain the presence of gas when it could not be detected by the sense of smell was one which brought the air supposed to be contaminated with gas into contact with a strip of paper sensitized. When the gas is present this becomes discoloured, and the depth of discolouration, ranging from rose pink to black, indicates approximately the percentage of gas in the air.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO, of Toronto, Limited. Publishers,

Confederation Life Building, - TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

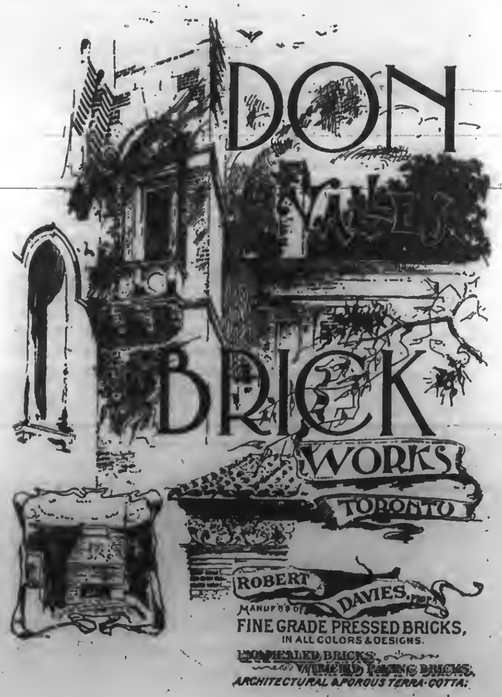
NOTE.

Mr. Vincent Groom, of Llanrug, Wales, is said to have solved the problem of the disposal of the refuse of slate quarries by perfecting a process by which, it is claimed, the waste can be made into solid blocks, capable of taking a highly-glazed surface in any number of colours. It is claimed that the new substance thus produced will stand a pressure of 100 tons to the inch—more than any natural stone—that it will be lighter in weight, and can be placed on the market at a cheaper rate than ordinary tiles.



NOTES.

A writer who has demonstrated the fact says that 3 pecks of lime and 4 bushels of sand are required to each perch of 22 cubic feet of masonry when built in a wall.

The belfry of the fine old cathedral at Chartres has been found to be in a defective condition. By the winds of centuries and the vibration of the bells the masonry has become dangerously insecure. Repairs are to be promptly made.

In connection with a recent discussion before the Boston Society of Civil Engineers on Foundations Mr. E. W. Howe mentioned a novel method of driving inclined piles in foundations for the Atlantic Avenue bridge by the aid of a steel case 13 inches square and 39 feet long placed at the desired inclination. With this apparatus 95 piles were driven in 10 hours. Mr. R. A. Hale mentioned a chimney 225 feet in height imposing a load of 2,250 tons on an area of 1,225 square feet, the foundation being sharp river sand 19 feet below the surface of the ground, into which piles had been driven to a depth of 5 feet; allowing for wind the extreme pressure is 2.4 tons per square foot and no settlement has occurred.

The United States Fidelity and Guaranty Company, one of the largest, strongest and most favorably known surety companies on this continent with a cash capital and surplus of over three million dollars have established their Canadian head office in Toronto at 6 Colborne st. The joint managers are Mr. Arthur E. Kirkpatrick, one of Toronto's most enterprising young business men, and Mr. J. A. Kennard, late of Baltimore, a lawyer of experience and ability. The bonds of this Company are accepted by the Canadian Governments, municipalities and by railroads and corporations in all cases where a bond guaranteeing the specific performance of a contract is required. They are prepared to furnish bonds at once up to any amount.

It has always been a wonder to us why architects should be so fond of the blocked column, for to our mind it is an ugly feature. It has neither the solidity of the pier nor the grace of the column, and always produces a lumpy effect. The lines of the column are quite spoiled by the clumsy-looking blocks, strung like so many chunks on a rod. We can call to mind a score of buildings which are marred by this feature. Without doubt it has been used by architects of great eminence, but that does not change its inherent defects. And not only is it ugly, but the additional cost of the stone is considerable. We should like to see it altogether abandoned, and, in place, either a solid-looking pier or a column with its graceful lines uninterrupted from base to cap. But we fear the blocked column is being increasingly used rather than set aside, probably more for ill-considered fashion than deliberate choice. Ill-considered fashion is not a thing to foster.—Building News.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingles stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

TERRA COTTA FIREPROOF BUILDING MATERIAL

POROUS TERRA COTTA among underwriters is classed as preferred risk, and the schedule of rates now enforced in the city of New York shows a difference, often great, which, computed means an annuity on large sums of money.

This indisputable fact appeals to architects as representing clients who may soon be exposed to the same classification in Canada. An apparent saving in selecting cheaper fireproof material may be more than lost through increased insurance cost.

POROUS TERRA COTTA FIREPROOFING is a credit to the buildings in which it is used and increases their selling value.

O. A. A. EXAMINATIONS.

The Examinations of the Ontario Association of Architects were held in April. The following were the successful candidates:

1st Examination.—Messrs. W. F. Sparling, L. C. Montizambert and Edwin Menger.

2nd Examination.—Mr. J. A. Mackenzie.

PAINTERS' AND DECORATORS' CONVENTION IN TORONTO.

At the Ninteenth Annual Convention of the National Association of Master House Painters and Decorators of the United States and Canada, held in Richmond, Va., in Eebruary last, a cordial invitation was given the Association by Messrs. Jas. J. O'Hearn and Stewart N. Hughes, President and Secretary of the Toronto Association, to hold its convention of 1904 in Canada's Queen City. The invitation was backed by a letter from the Mayor of Toronto, and was accepted. Mr. Hughes was elected a member of the Executive Committee.

TESTS OF MATERIALS.

The care exercised in Germany to demonstrate the qualities of materials employed in construction, is illustrated by a recently published report of the operations of the Imperial testing station at Charlottenburg. During the year in question 32,580 tests were made, against 31,982 tests in the preceding year. Some of these were carried out at the request of foreigners. Of the 1901 tests 20,391 were of binding material; 12,189 of various kinds of stone. Armed cement was especially dealt with. But many tests were made with trass-lime mortar. There was a considerable increase in the number of samples of lime sandstone, showing that this is coming into use. Another notable feature of the tests was the number of samples of jointless flooring in imitation of linoleum and woodword. For this purpose for the first time the sandblast has been employed in producing patterns on these materials. A committee appointed by the Minister of Public Works and for Trade and Commerce was charged with the testing of gypsum; samples are being obtained from abroad as well as at home.

FIXING TILES.

The general custom nowadays, says the Builders' Record, seems to be to use copper nails for fixing tiles or stone slates, that is, in work where some little pretention is made to doing the thing well. Of course a speculative builder uses the cheapest thing he can get hold of so long as it lasts long enough for him to sell the house, and he may use iron nails unprotected or perhaps coated with tar. If he adopts galvanized iron nails he no doubt considers he is doing the thing handsomely. But let the conscientious architect avoid being misled into them by the persuasive builder. Zinc or composition nails are better—but not good enough. Wooden pegs seem to have gone out, but they were fully as good as iron nails. In some ancient buildings the tiles were fixed with splinters of bone, and excellent they were for the purpose. And now another instance has recently been offered by a writer in the daily press of an old building at Mansfield which was a good many years ago roofed with stone slates fastened with hundreds of the prongs or tynes of the antlers of deer. They were pegged into holes pierced in the slabs—two to each slate—in the ordinary way. Their use was evidently traceable to the ancient builder's desire for quaintness. It is these little tricks and fancies of the old workmen which more often than not give the quaintness and charm to old country houses so much admired by all our architectural students. All the striving after effect so characteristic of to-day does not make up for the interest we derive from the evidences of the loving hand and thoughtfulness and resource of the craftsmen of old.

Cassidy—Oi want a wreath av flowers, an' put on it, "He rests in pieces." Florist—Don't you mean "He rests in peace?" Cassidy—Oi mane phwat Oi sed. 'Tis fur Casey, thot was blowed up in the quarry.—"Tit-Bits."

New Process of ARTIFICIAL MARBLE
(In Keen's English Cement.)

I wish to lay before the public notice that I am now manufacturing Artificial Marble and that I have to that effect secured the services of Mr. Geo. F. Simpkin, who has had over 12 years experience with the leading firms of this special work in the United States and England. I am now prepared to undertake the manufacture of Artificial Marble Columns, Church Altars, Shrines, Bases, Capitals, Pilasters, (plain or fluted), Decorative Mantels, Dadoes, Pedestals, Etc. Samples of this work can be seen at my office or factory, 304 and 308 St. Joseph St., St. Roch, Quebec City, and at the Hochelaga Bank, M. S. Foley's Bellevue Apartments, Metcalf St., H. Morgan & Co., and Art Rooms, Philips Sq., Montreal.

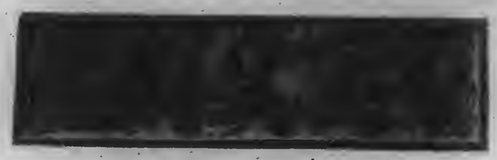
Jarvis Concrete Block Machine Company

McKinnon Building Toronto Canada



ROCK FACE BLOCK [Patent Pending.]

DUCK BILL TOOLING [Patent Pending.]

CROSS TOOTH CHISELED [Patent Pending.]

TOOLED FACE BLOCK [Patent Pending.]

These are facings that the Jarvis Machine will cast, besides three other rock faces not shown here.

This is the Concrete Era. Concrete made of Portland Cement, sand &c., is fast superseding natural stone, as well as brick and steel for buildings, and all kinds of constructions, such as bridges, dams and foundations of every description.

In view of the foregoing facts a Company has been formed for the purpose of manufacturing machines of all descriptions, for the making of concrete constructions.

This Company has acquired from Beaumont Jarvis, Architect, of Toronto, Canada, several of his inventions and patents, relating to machines for forming concrete walls, and concrete facing stones for buildings.

The science and art of manufacturing concrete building stones has advanced with leaps and bounds, so that with any of our machines in one simple operation, durability, beauty, economy, and sanitation together with insulation from heat, cold, damp, or sound, is absolutely effected since a hollow wall is perfect proof against heat or cold, and concrete is stronger than brick and more durable than most natural stones; any prominent Engineer will verify that.

For a few hundred dollars any one may equip a plant with these machines which will absolutely dispense with the manufacture of brick buildings, having the appearance of natural stone, at about the same cost as brick.

One block has the same cubic capacity as about forty bricks, so that it must necessarily cost so much less for the laying of our hollow blocks per cubic foot than for brick. Then again, the walls being hollow, the building must necessarily be lighter and stronger because concrete is stronger than brick and the hollow space makes the wall lighter than a solid wall.

We have in our employ an architect, engineer and artist. Without these no artificial stone or concrete stone company can have any great success and those who buy our machines will have full instructions, and the benefit of their knowledge as to manipulation. We also employ none but the very best machinists and foundry men, and skilled mechanics in every branch.

For fifty years concrete stone has been used in England for the facing of many important buildings and stands to-day, without any apparent weathering.

At the present time in France many important buildings have been faced with concrete stone and also many cities throughout the United States and Canada.

JARVIS MACHINE SHOWING MOULDED HOLLOW BLOCK
[Patent Pending.]

This hollow block is a registered design, and was invented by a practical architect, Mr. Beaumont Jarvis, of Toronto, Can. The object of this invention is to make a stone facing to a wall, having a hollow space, which is a non-conductor of heat, cold, or sound. The advantage of the hollow cement blocks made by the Jarvis Concrete Block machine, as compared to other blocks is in the fact that it only requires one half the time and labor to manipulate the machines than any other on the market. The new machine is more simple, and one half the expense of any other.

We supply with each machine six plates, so that the stone cast by the Jarvis Concrete Block Machine may have any tooling or rock face that may be required, the same as the natural stone. The size of the stone is 8" x 8½" x 24" 6", or in case of hollow blocks the size is 8½"x10"x30". Three men doing their own mixing without any other machinery, can make from 100 to 150 blocks per day, which is equal to 250 to 350 feet.

The above block is a registered design, and any one infringing on this will be prosecuted, and a reward will be given to anyone for information that will lead to the conviction of any person or persons infringing on the said invention.

These blocks can be manufactured at about 11 cents per foot, and sills and heads should not necessarily cost any more.

Most natural stone costs from sixty-five to eighty-five cents per foot. Is it any wonder these blocks are bounding into popular favor?

The Jarvis Concrete Block Machine Company is also prepared to undertake all kinds of concrete construction such as dams, bridges, and foundations of all descriptions.

The Portland Cement industry throughout the world is developing to stupendous proportions and has superseded natural stone in addition to wood and steel.

A properly made concrete stone should have all the appearance of natural stone, and every engineer is aware that concrete is everlasting.

The Pantheon, at Rome, has a concrete dome of 142 ft. in diameter and has weathered the storms and other destructive influences for nearly two thousand years and is to-day, apparently, in as good a condition as the day it was built.

In England, where natural stone was used for facing and concrete for the backing, the natural stone has crumbled away and the concrete backing, which was intended to play the secondary part is better than ever.

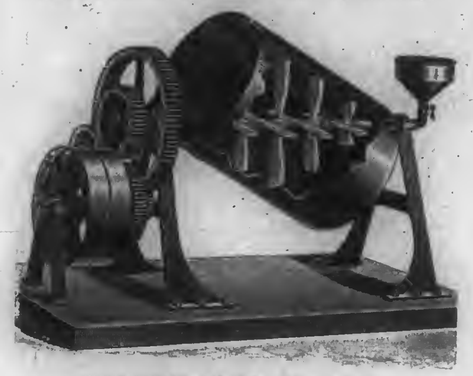
JARVIS CONCRETE BLOCK MACHINE COMPANY - McKINNON BUILDING, TORONTO, CANADA

Jarvis Concrete Block Machine

PATENT APPLIED FOR

JARVIS SILL MACHINE READY FOR USE. [Patent Pending.]

MACHINE OPENED SHOWING CAST WINDOW SILL [Patent Pending.]



JARVIS CONCRETE MIXER. [Patent Pending.]

JARVIS SILL MACHINE OPEN [Patent Pending.]

Concrete Mixer

This is the best Concrete mixer known. Each revolution without the aid of the blades inside will turn over the mix four times in the opposite direction to one turn the drum, should make it equal to about 16 turnovers at one revolution of the drum.

The only way to get a good concrete is to have the proper proportions of cement and sand &c. well mixed—men with shovels are not always reliable, and most mixers on the market are still more unreliable than the men. The mixer may be run by hand or motor power.

The axle of the machine is hollow and perforated, so that the water is sprayed gradually into the mix—any other method does not give the best results.

A FEW INTERESTING POINTS

It is only a drum having the axle going diagonally through and having blades revolving in opposite directions.

A gentle spray is gradually sprinkled through the mix by pouring the required number of pails into the hopper.

There is nothing to break off the blocks as in some mixers.

It is the most efficient and up to date mixer, doing the quickest work of any on the market.

There is nothing complicated about it.

Jarvis Concrete Wall Mould

is an invention for the forming of concrete walls for foundations, also bridge piers, dams, &c., &c.

The usual way of building Concrete walls by using scantling and boards is very crude and expensive and also difficult to get straight and plumb.

By this method and device the mould box is moved along the wall thereby actually casting individual stone of any breadth, length, width, or depth in position in the wall.

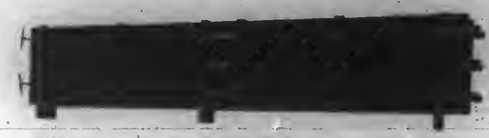
This ingenious device telescopes in every direction and may be 16 feet long if necessary.

In three days the next layers of stone or concrete may be cast so that if your mould box is 3 feet deep it means only twenty days to build a wall 20 feet high.

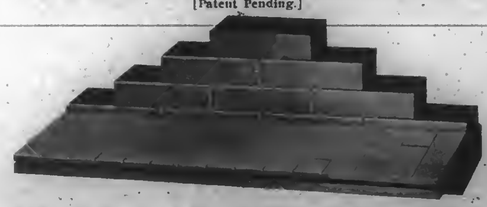
The size of the building does not signify as it only means more moulds and more gangs of men.

Further particulars will be sent to the purchaser with each machine.

JARVIS CONCRETE BLOCK MACHINE COMPANY



JARVIS MOULDING FORMS FOR MONOLITHIC CONSTRUCTION
[Patent Pending.]



JARVIS METHOD OF CONSTRUCTING FOUNDATIONS AND BASEMENT FLOORS.
[Patent Pending.]

It can be seen from the above cut that walls and floors formed in this way are absolutely non-conductors of heat, cold, damp and sound. There are 3 air spaces in the walls. Walls of this construction will cost less than brick.

If a whole house were built in this way a great saving of fuel would be the result.

The Jarvis Concrete Block Machine Co. is prepared to arrange with parties to sell district rights, and is also prepared to appoint agents in various districts, who will be allowed a liberal commission for any sales they make.

THE JARVIS TELESCOPE MOULD BOX

This mould box is a telescoping arrangement, so that a stone of any length, breadth, depth or height may be cast. It is also applicable for moulded sills courses or any moulded course by simply dropping down in the bottom of the box a reverse wood mould of what the stone casting is to be. This is probably one of the most ingenious devices ever invented for the concrete stone industry and bids fair to revolutionize all other forms of moulds for casting stone.

Canadian Building Materials for Japan.

The Hon. Sydney Fisher, who has recently returned from a visit to Japan in connection with the exhibit which Canada is to have at the Osaka Exhibition, states that a market exists there for various lines of Canadian products natural and manufactured. These include lumber, furniture and sheet metal building material. The Japanese Minister of Education was greatly impressed with the adaptability to school building of the metal roofing and ceiling material forming part of the Canadian exhibit, and promised to send one of his architects to inspect it.

Brick Tests.

The result of a series of tests made to determine the weak points of bricks under different conditions, was recently presented to the American Society of Civil Engineers in the form of a paper containing numerous tables and illustrated by photographs and diagrams. Tests were made for compression, tension, bending shear and torsion, the following being shown to be the order of increase in strength: Tension, shear, torsion bending compression. Further the tests showed that water does not cause deterioration in strength, while reheating greatly improves the quality.

Effect of Climatic Conditions on Cost of Building.

The opinions of more than twenty-five representative Canadian architects and contractors as to the relative advantages and economy of finishing buildings in winter and summer, are printed in the present number. The subject is considered from every point of view. The letters make interesting and instructive reading, and should help to settle in the minds of building owners, architects and contractors, an important question on which there has hitherto been wide divergence of opinion. The consensus of opinion expressed by our correspondents is strongly in favor of the advantage of summer work. Many good and apparently sufficient reasons are given in support of this view, although the minority who hold to the opposite belief, are not without reasons to support their position. There are many questions of perhaps equal importance on which a comparison of experiences would be profitable.

Fireproofing That is Not Fireproof.

The destruction of the Roosevelt Building in New York teaches that it is useless to spend money in fireproofing buildings unless every detail of the work is thoroughly done. This building was supposed to be

fireproof. The floors were of steel beams and terra cotta arches, the flanges protected and the space above the arches filled in with concrete. It had a tile roof. But, one of the elevator shafts was unprotected, the columns supporting the different floors were of cast iron, unprotected, and there were numerous partitions glazed in the upper portion with ordinary glass. These caused the destruction of the building. The fire shot up the elevator shaft, the unprotected cast iron columns and glass partitions cracked and gave way, letting down the roof and upper floors, which in falling broke through the lower floors. Fireproofing done in this manner is not only a waste of money but the destruction of the buildings thus carelessly constructed has weakened the confidence of the underwriters and the public in the possibility of making buildings fireproof.

Strikes in the Building Trades.

The Engineering Review hits the nail on the head when it says: "The building trades seem to have rooted objection to work. At least, history shows that whenever there seems to be an excellent chance for them and their employers to make some money they, more than any other class of working men, make demands which tend to restrict building operations and throw themselves, or many of themselves, out of work." The truth of this statement was never more forcibly illustrated than this year, when the prospects for an unusually prosperous season have been to a large extent blighted by strikes. It is a pity that the wisdom of the axiom "make hay while the sun shines," is so foolishly disregarded by the workman of to-day. When the summer is ended and the coal bin needs replemishing it will perhaps begin to dawn upon the strikers that they would have been better off had they worked steadily all the year at a few cents an hour below what they demanded and were refused. Labor, unlike many other commodites, cannot be stored away and sold, perhaps at a greater profit, at a later date. The workman who refuses to sell his labor to-day is out of pocket for all time the money he might have obtained for it.

Peculiarities of Bricks Composing the Campanile.

Some interesting data, gathered from careful examination of the bricks used in the construction of the fallen Campanile at Venice, is said to have been presented in a recent lecture by Commendatore Boni to the History Congress at Rome. The lecture was illustrated by drawings. The bricks are said to have been manufactured in the first century, not from kneaded and compressed clay, as at the present day, but from slices of the natural clay. On this account each individual brick is believed to have a supporting strength four times as great as the bricks of to-day. The lecturer exhibited specimens of bricks which he had had made out of Roman clay in the same manner as the ancient ones, with the object of showing that the new Campanile might be built of the same enduring material as the old. Some of the ancient bricks are curiously marked with figures, numbers, private marks and letters. Signor Boni infers from their shape, texture and general appearance that they were made not by the Venetians, but by the Romans, and prior to being built into the Campanile had been used in fortifications and other forms of construction.

The Duty of Committees of Award.

Messrs. G. F. Bodley, R.A., and R. Norman Shaw, R.A., assessors in the Liverpool Cathedral Competition, have presented their report. They give first position to the design by Mr. Gilbert Scott, grandson of Sir Gilbert Scott. The Builder states that Mr. Scott's design entirely ignored an important condition set forth in the instructions to the competitors, viz., that the plan of the cathedral should provide for a wide open space for a large congregation within hearing of the preacher. It is probably for this reason that the Committee have expressed their intention not to accept any of the designs. We were surprised not long since to hear several architects engaged in conversation about competitions, state that it was their practice when preparing plans for a competition to ignore the limit of cost set for the proposed building. It is manifestly unjust to the competitor who honestly strives to strictly conform to all the conditions laid down, and who perhaps is hampered because of his conscientiousness in this regard, that his design should be passed over in favor of the man who sets himself to produce something which will catch the fancy of the assessors, regardless of the conditions.

ERRATA.

Through oversight the name of Mr. Frank Darling does not appear on the illustration sheets in this number showing views of the interior of the Canada Permanent and Western Mortgage Company's Offices and Board Room, Toronto. Mr. Edwards writes that Mr. Darling and himself were joint architects in the planning of these improvements.

EMPLOYMENT WANTED BY BRITISH BUILDING MECHANICS.

538 Oxford St., London, W., England.
May 31st, 1903.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

Sir,—Hearing that men are wanted in the building trades in Canada, may I suggest to you the formation of a similar society to the "Canadian Farmers Help Society." There are many men of good experience with references as to their workmanship and reliability who are quite unable to get good permanent work here in London. The work that is offered is so desultory and has no permanence except in a minority of cases. Taking myself as an example, I have had three and a half months work this year, and although I have worked to my employers' satisfaction and have good references, I am quite dependant on taking my chance with two or three hundred other applicants for the very few berths on offer here in England. Should you consider this any further or care to throw your columns open to a few advertisements from men in London wanting work in Canada, I feel sure that there would be many hundreds of men to avail themselves of your kindness. Thanking you in anticipation.

I am Sirs
Yours sincerely,
ROBERT H. BAKER.

[There is at present a brisk demand in Canada for building mechanics, as well as mechanics of all kinds, but the trade unions are demanding higher wages and shorter hours, and are strongly objecting to mechanics being brought in from Great Britain. There is no doubt, however, that competent workmen coming here at the present time would be certain to find employment at fair wages. We hope that some of the workmen who find it difficult to obtain regular employment in London, may find their way to Canada. If they are competent and sober, they can rely upon getting employment.—EDITOR, C. A. & B.]

NOTES OF TRAVEL.—I.

A LONDON HOUSE AND ITS SURROUNDINGS.

The accompanying plan shows a typical west end house of the smaller size in a good neighborhood.

VIEW OF FRONT OF HOUSE.

The plan itself is interesting, and to my mind shows a true elegance obtained by dispensing with certain conditions which are usually, in Ontario at any rate, considered to be indispensable in the plan of a first-class house. In the first instance the single flight of stairs will attract attention. It is considered, with us, a matter of the first importance that every house, no matter how small, that pretends, though a cottage, to

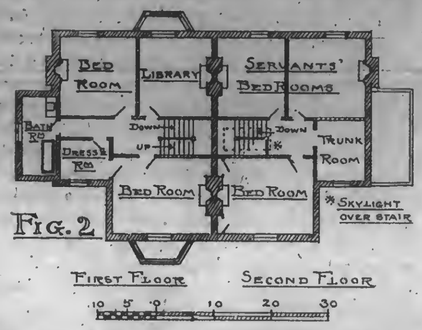

FIG. 2.

be "a cottage of gentility," should have a back stair.

The greatest pains can not prevent this stair injuring the simplicity of the ground floor, and thereby adding to the cost to an extent that does not appear in the cubical contents of the staircase itself; and unless sufficient space is taken to disconnect it from the kitchen it is a sure means of conveying the smell of cooking from the kitchen to the rest of the house. The gains on the other side are that servants will not be encountered on the stair from ground to first floor, which is the extent of the back stair in this sort of house, and that the stair carpet on this stair lasts longer. The latter point must be yielded; but, if the stair is well placed—as it is in the example here given—the passage of servants is no real trouble. In the old days, when slops had to come downstairs to be carried out of the house, the back stairs had a reason for existence even in small houses; but now-a-days there is no actual traffic on the main stair during the day. It affords a means of access to the housemaid's up-stairs work; that is all. As far as the approach to the servants' bedrooms goes, it is generally conceded that this should merge in the family lines of communication for some part of its way, and that communication with the kitchen should not be too easy. It seems therefore as if too much can be made of the desirability of a back stair, and that a retired arrangement of the main stair, something after the manner of the stair in this plan, might be substituted with advantage for small houses.

The principal reason however, why the ground floor, in the plan before us, is so simple is that it has no service rooms. It would be undoubtedly better, for easy service, and the care of glass and china, to move the lavatory back and the entrance and dining room to the right and slip in a service pantry entered from a sort of back hall, formed under the stair landing by moving the door at the head of the stairs to the face of the landing at the return. But how this spoils the hall, complicates the plumbing and makes tight work of the entrance and area steps, taking from

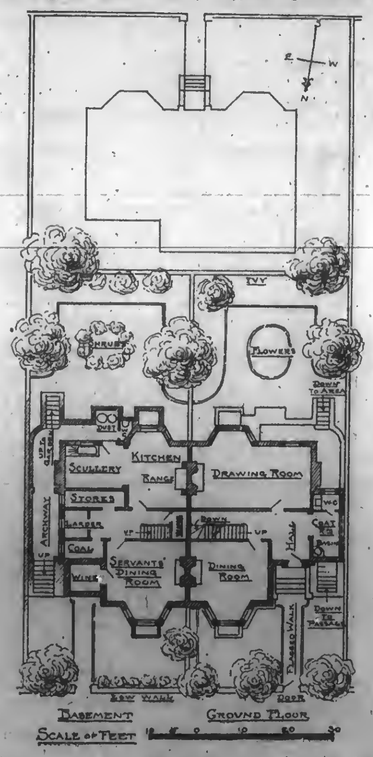

FIG. 1

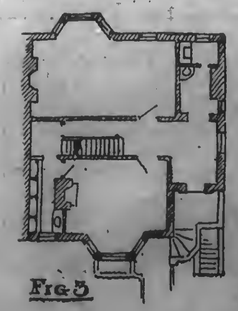

FIG. 3

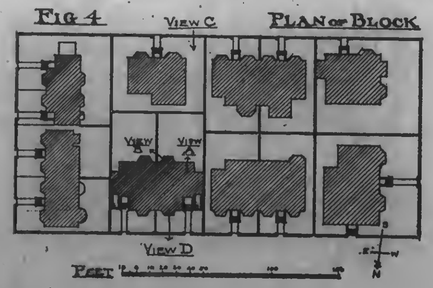
them their present dignity! There is however no doubt that the ground floor service room should be managed somehow. It is quite otherwise with the kitchen; the beauty, not only of this house, but of the whole neighbourhood, lies in the basement kitchen; and here is the point best worth considering about the London house. With us it is considered a matter of necessity, for the sake of easy service, to have the kitchen department on the same floor as the living rooms and the front door; but how much we suffer in consequence! The service rooms are pinched to the last degree yet without preventing the living rooms from being pinched too. The kitchen must, except on a prohibitive scale of cost for land, share the best floor with the best rooms; intrude a perceptible presence among them; and condition their arrangement and lighting. In other words the family suffer in order to give advantage to the servants. What is this advantage? It is not an all around advantage. Cramped quarters are no gain to the servants, nor are they any happier for being so close to the living rooms. It is chiefly for convenient communication with the dining room and the front door that the kitchen department is placed on the ground floor; and the insertion on the ground floor of a serving pantry, with a sink and with cupboards for china and glass, fairly meets this necessity; for the maid, whose duty it is to attend to the front door during most of the day, will have her special quarters in this pantry. If ease of service for the dining room and front door is met in this way, the balance of advantage seems to be in favor of a basement kitchen, merely from the servants' point of view; for there will be ample quarters, isolated and distinct, and comfortable in summer as well as in winter. We are apt to think of a basement as a damp and dreary place; and so they are in houses where the basement is not used, and is not built for use; but these high, airy and dry English basements are quite another thing, and indeed it is more sanitary for the rest of the house that the cellar should be kept warm and dry by being occupied. But the great gain is in point of beauty and cost; larger rooms on the ground floor for the same money, and every room with a free look out.

It is in the matter of look out that the London house is such a useful study of how to make the most of a town lot. It is not an individual work; all the houses in the block must be planned with the same idea: If the custom is not already established it is a case for building restrictions; and in the borough of Kensington, where the house before us is situated, the law comes in also forbidding the drying of clothes in gardens. The result is a block of buildings as in Fig 4.

The kitchens are all invisible and there are no back yards—except in the American sense of ornamental ground. Ashes and rubbish are placed in two large cans which have a place of their own, outside in the kitchen area of every house, where they are concealed from view, but readily accessible to the dustman on his rounds. Rag and bottle men and all kinds of waste



users also thrive in London. The result is a clear area, on both sides of the house, which is devoted to trees, shrubs and flowers in borders, and either paved or tamped hard with London red earth mixed with gravel. The street fence is a low wall, usually of brick plain or stuccoed and painted like the house. The divisions inside the lot are often of inconspicuous iron. Sometimes there is a stone or terra cotta balustrade on top. An interesting feature is the gate which rises up between posts, no matter how low the wall is, and is

FIG. 5.—VIEW FROM DRAWING ROOM WINDOW.

more often than not a solid door. Sometimes this door is kept shut and can be opened from the house when the bell is rung. The bell pulls are usually in any case in the gate post, in beautifully kept brass; there are a pair,

FIG. 6.—FROM DRAWING ROOM BAY WINDOW.

one labelled "visitors" and one "tradesmen" so that the servant within knows whether to go to the door upstairs or downstairs.

W. A. LANGTON.

RELATIVE COST OF DOING WORK IN WINTER AND SUMMER.

A difference of opinion seems to exist among architects and builders as to whether the inside work on a building can be done more cheaply in winter than in summer, and whether a contractor is justified in submitting lower tenders for such work to be done in winter. The arguments pro and con will be found in the following letters recently received from representative architects and contractors throughout Canada:

TORONTO, April 29th, 1903.

I consider the contractor is justified in submitting a lower tender for work on a building to be executed in the winter season. At the same time my experience and observation has been that a client who is obliged to pay for caretaker and for fuel during the construction, also for loss of interest on the work, does not save anything thereby. My advice in future will be for my client to make as early a start as possible in the Spring, and excepting strikes, I think that his work would cost less and he would be farther ahead by the end of the season.

GEO. W. GOUINLOCK.

TORONTO, April 30th, 1903.

With respect to plastering in winter or summer months would say that the extra cost for plastering in winter as against summer is about 2 per cent., but occasionally a contractor being slack and wanting to keep his men employed will cut the figure a little for that particular purpose. This does not include furnishing heat which would still add about 4 per cent.

J. M. GANDER.

MONTREAL, April 30th, 1903.

As to the comparative advantage of doing inside iron work in winter or summer, we may say that according to our experience there is very little difference. There may be an apparent difference in lower wages in the winter, but taking the cold into account, which frequently prevents men from doing their best, and the cost of heating, which is a large item, it brings the cost of producing the work up to the highest summer level. In summer wages are somewhat higher, but the conditions are more favorable for doing work, and men will accomplish more than in the winter; therefore we consider that there is no difference from point of cost in either winter or summer.

H. R. IVES & CO.

MONTREAL, April 30th, 1903.

As a result of an experience of sixteen years in the business, I am prepared to say that inside work on buildings of the fireproof class can be done cheaper in winter than in summer, and as far as terra cotta fireproofing is concerned, the winter job is both better and cheaper.

And I have every reason to say that terra cotta fireproof arches, and partitions that are built in winter with a reasonable amount of care are certainly stronger and better in every sense than it the same class of work was done in summer time especially if the terra cotta blocks are kept dry. I claim that there is a better unity between the cement mortar and the blocks than could possibly be obtained in the summer time. I claim this from the reason that the arches in the roof of the Royal Electric Sub-Station in Montreal were placed in position in the month of February 1902 and the plasterers plastered the ceiling in March—the following month—the said roof was about 60 ft. in the clear above the ground floor and the contractor experienced no difficulty whatever. And also the floor arches, the roof, the partitions, etc., of the Guardian building of this city were placed in position between October and February and no doubt the workmen made a better average per nine hours day, and the work is certainly better than could be obtained if it had been done in the summer.

N. T. GAGNON

LONDON, ONT., April 30th, 1903.

With reference to difference in the cost of doing the inside work on a building in winter and summer, would say my opinion, from past experience, is that the work can be done more cheaply in summer for several seasons. In the first place it is necessary to keep fires going to keep the building warm in winter, and we have found that this occupies a considerable portion of the time of at least one man. The fire would invariably be allowed to go out during the night, and have to be put on fresh in the morning, which would mean that the house would be too cold for working for perhaps an hour or more. In addition to this the days being much shorter in winter, it is often impossible for the workmen to see the work properly after 4.30 in the afternoon, whereas in summer there is no objection of this kind. Of course the wages paid are the same per hour summer or winter, so there is no difference in that respect.

S. STEVELY.

LONDON, ONT., April 30th, 1903.

Replying to yours of the 29th, I would say no, the inside work on a building cannot be done more cheaply in winter than in summer, because labor costs the same in winter as in summer. From my own experience, at times I have taken work lower in winter to keep my men employed.

Regarding finishing a house in winter I think the work is much better done, and more satisfactory to the proprietor, as the building must be heated, which dries out the timbers, and with our present heating system greater care has to be taken to prevent shrinkage. A good house I always recommend to be finished in the winter.

WM. TYTLER.

MONTREAL, May 1st, 1903.

I cannot see the economy there may be, in doing inside work in winter instead of summer. Inside work may be considered to be: Plaster work, joinery, painting and glazing, plumbing, gas, electricity, heating.

Plumbing, gas, electricity, heating could be done any time and the quality may not suffer thereby. As to strict economy I don't believe there is any, as working hours are shorter in winter than summer and the wages are as high in winter as summer. It is very well known, at least here in Montreal, that although plaster work is done all through winter, it does not give so good a job and the expense for heating while the work goes on must be added to the regular price.

And should working hours apply just as well to that trade as to others:

As to joinery work, short hours apply, and to have real good work heating must be used, consequently adding to the expense—I don't believe there is any economy on that head. Painting, although not so much affected as joinery from the cold and moist weather, is not I believe done more economically in winter than in summer. As a whole, winter work is a necessary evil, that's all.

JOS. VENNE, Architect.

MONTREAL, May 2nd, 1903.

In reply to your equiry I am of the opinion that the season is no factor in prices. Formerly it was so, when wages were lower in the winter.

WM. E. DORAN, Architect.

LONDON, ONT., May 1st, 1903.

My business it is all outside work and from 26 years experience I find that winter work does not pay unless I get more money for the work than I do in the summer.

JOHN WHITTAKER.

TORONTO, May 2nd, 1903.

Inside work I think, cannot be done with less cost to the contractor in winter than in summer, but it is frequently done I am sure with less cost to the owner, for the simple reason that the contractor, to keep things moving in slack time, takes work cheaper. Every architect is familiar with the carpenter's expression, "Well, we're not very busy now, and could do work cheaper than if left till spring." Whether a contractor is justified in submitting lower tenders in the winter than in summer depends on the facilities of the individual contractor. As the conditions under which the work is done in winter vary more than in summer some would be justified while others would not, in taking work cheaper.

HENRY SIMPSON.

TORONTO, May 2nd, 1903.

In answer to your question I would say that in my opinion work can be done more cheaply in summer at the present time. Some years ago during the dull times workmen were willing to

work for lower wages during the winter season and work could perhaps under those conditions bed one more cheaply, but those conditions do not prevail at present.

R. G. KIRBY.

MONTREAL, May 2nd, 1903.

My experience in over twelve years practice as an architect is that the inside work of a building can be done cheaper in winter than in summer. I believe the reason of this is, that the building operations are more active in summer than winter.

ALCIDE CHAUSSE.

QUEBEC, May 3rd, 1903.

Replying to your enquiry of April 29th, I beg to state that all things considered, I do not see how the inside finish of a building can be done cheaper in winter than in summer, the only difference in favor of the former being a slight increase in cost of labor, practically compensated for by the shortness of working hours and the extra cost and inefficiency of artificial light, to which must be added the cost of heating, which comes very high in an incomplete building. That is my own experience, and I hear it has been strictly confirmed by the experience of contractors on our new theatre, the Quebec Auditorium, where the cost of heating, even under normal fuel rates, would still have overeaten the saving on winter labor.

G. E. TANGUAY.

MONTREAL, May 5th, 1903.

Re price of summer vs. winter work, I would say that I would not be an authority on the question of inside work. With regard to our roofing, of course there is a heavy difference in cost, although we cannot obtain any better price for doing it. Our Montreal winter season's work costs us fully 20% more than the same work during the summer weather.

C. T. WILLIAMS.

TORONTO, May 5th, 1903.

I have always found that men working on buildings always work better during the summer than in the winter They enjoy the fine weather and are in better spirits, can keep their tools in better order. Material can be got in better, while on the other hand, no matter how comfortable a building may be enclosed during the winter, there is always a certain amount of running in and out, dampness in the building, the difficulty of getting to work on time in bad weather, all of which affects the men, and I have always found that I could do my work better and cheaper during the summer than winter and do not consider that any contractor is justified in taking contracts cheaper in winter, the wage question being equal.

H. MARTIN.

TORONTO, May 7th, 1903.

My experience has been that winter work is slightly cheaper. Wages in both seasons are the same, but mill work would be cheaper during the winter months, as the factories prefer to keep running on, taking work at low figures rather than stop machinery or lose good men; and the contractors also prefer to keep going for less returns in order to keep their men together. I prefer winter finishing; on account of the scarcity of work there is a chance to get the better class of mechanics, and the temporary heating of a building is preferable to finish in rather than the changeable atmosphere of summer. My experience has been, without exception, that interior work stands better when done during winter months, and under conditions that are most trying to such work, namely, when artificial heating is being used.

W. L. SYMONS.

MONTREAL, May 7th, 1903.

My experience is that with a climate like ours it is cheaper to do work on buildings in summer than in winter.

In winter buildings require to be heated to prevent water and steam pipes from freezing, also all plaster and mortar of all kinds has to be more closely looked after than in summer, and even if there were no water or steam pipes, plaster and mortar to freeze, the building not being heated there would be dampness which would cause lumber to twist and warp. I am of the opinion that all building trades require more attention in winter than in summer, therefore conclude, building operations are more expensive in winter than in summer.

JOHN WIGHTON.

VANCOUVER, May 5th, 1903.

The writer's experience is that winter finishing is more expensive than that done in summer. Heating, special care of the premises and waste of materials all have to be taken into account, also time for completion, interest on money in the event of the work being prolonged. Winter work means that painting or other branches will be delayed for spring, hence extra time is required. A contractor under certain circumstances might be able to figure lower for winter, especially if sub trades are done by contract and special reduction made to have work going on during the dull season. Over here in British Columbia we consider a contract requires a higher figure, but localities differ in this respect. My advice would be do everything possible during the summer months, put on extra men and rush the work—save time and save money.

E. COOK.

WINNIPEG, May 8th, 1903.

I consider it worth from 10 to 15% more to finish work in winter than in summer, besides getting a better job done in summer.

W. F. LEE.

MONTREAL, May 16th, 1903.

We know that in our line it costs less to do our work in the summer than it does in the winter. The long light days and the more comfortable climatic conditions are all in favor of summer work. It used to be the custom to reduce wages in the fall, which has probably given rise to the cheaper idea. But men now get as much per hour in winter as in summer.

J. W. HUGHES & SON.

VANCOUVER, B. C., May 7th, 1903.

Your enquiry of April 29th at hand. Will answer with few lines covering my observations for over twenty years—providing the wages paid per hour are the same in winter as in summer. I consider the work will cost at least fifteen per cent. more in winter than in summer, and in seven out of ten cases, the finished work does not give the satisfaction to owners or architects that the summer work would have given at the less cost. The imperfect light in most parts of the building for two to four hours each day (although men are only working from 7 to 8 hours daily), the imperfect heating and drying of most buildings, during finishing; the extra amount of time required in cleaning and caring for the finishing materials are the chief contributors towards their extra cost. Under conditions favorable towards contractors, with an oversupply of labor to select help from (only the best of men will be used) and the men anxious to hold their positions by working well and doing good work the fifteen per cent. extra cost referred to might be reduced to about five per cent. or in some cases brought even with cost of summer work.

C. P. SHINDLER.

LONDON, ONT., May 11th, 1903.

Yours of April 23rd received and the contents considered by the Board of Directors at their last meeting. They were unanimously of the opinion that building contractors were not under any condition ever justified in submitting lower estimates for winter work. The lack of proper light and heat are of course the two principal hindrances to work being done as cheaply in winter, and added to that in some trades, particularly bricklayers and plasterers, is the very great waste attendant upon winter work.

GEO. S. GOULD,
Secretary, Builders' Exchange.

VICTORIA, B.C., May 6th, 1903.

My experience as a contractor teaches me that work cannot be done cheaper during the winter months, than the summer months. The material is in better condition to work in the summer and much more easily cleaned to a smooth surface. In this climate we have considerable rain during the winter months; the atmosphere is damp and penetrating and buildings erected during the winter require fires to prevent dampness penetrating and swelling the inside finish. The dry saason has the advantage as to cost. We make no difference as to cost summer or winter.

H. C. MCKILLICAN.

SAN FRANCISCO, CAL., May 12th, 1903.

My opinion is very positive that work can be done inside building much cheaper in summer than winter in any

city in Canada. The climatic conditions in California, U.S.A., are such that it does not make much difference. In summer you have climate in your favour; your building is more accessable; it costs nothing for artificial drying; you have no frost to contend with and your men have no broken time. I know I was caught twice in winter time—once in Vancouver, B. C.—when building Molson's Bank the frost brought down the Bank ceiling, which was very expensive; this was four years ago; two years ago I was caught with Rossland Post Office in winter time, and in that case it cost over 25 per cent. more. Carpenter work likewise suffers as does also painters' as they are nearly always bumbugged waiting for plastering, etc.

THOS. BRADBURY.

VICTORIA, B. C., May 11th, 1903.

We can do work cheaper in summer, as everything is dry and in much better condition. The only reason that we know could be advanced for cheaper winter work is that there is not usually as much doing in winter, and rather than be idle, sometimes work is taken cheaper.

E. W. WHITTINGTON.

VANCOUVER, May 9th, 1903.

As far as our experience goes in this city, and we have been in the business for fifteen years, inside work costs slightly more and is not so satisfactory when done in winter—that is to say in the months of November, December, January and February.

1st. A striking feature of this climate is the dampness of these months, making it necessary to close in a building and provide heat; where there is a furnace it is simple, but in many cases temporary stoves are needed; either way means more or less extra cost, risk from fire and disfiguring of walls with smoke, etc. 2nd. The plastering in nearly all cases is not properly set and consequently many more cuts and marks will occur in it which can never be made as good as the original. 3rd. Creat care has to be exercised in getting the finishing lumber on the job in fine weather, and even then sometimes it is caught on the road in a storm which makes trouble, sometimes having to be renewed. 4th. As to labor, there is a steady demand for good men the year round, so that wages are the same, but the dark days are no profitable, for even though the hours are reduced to from 8 a.m to 4 p.m., there are still days when it is too dark before quitting time. With all these items against us, contractors here figure no higher for inside work coming in winter, for the reason that it can be pushed along, whereas outside work at the same time may drag with uncertainty, carpenters at the best not averaging more than three quarters of the time outside, and bricklayers less during this period.

BAYNES & HORIE.

TORONTO, May 9th, 1903.

My opinion is, 1st, you cannot make the same progress; 2nd, you cannot make the same job in winter as in summer. In winter it takes from 12 to 15 days to dry out the first coat of plastering before it is ready for the second coat, and that has to be done with furnaces, which means time and money that you have not to expend in summer. Also you have got to take into consideration waste of material in our line (plastering) which does not take place in summer. Therefore I fail to see how work can be done cheaper in winter than summer.

JNO. NELSON.

VANCOUVER, B. C., May 6th, 1903.

Re cost of inside work in summer v. winter. My experince is that there is very little difference. Where trade unions regulate the wages, making them the same per hour throughout the year as they generally do, I think the cost of inside work as well as outside work is greater in winter than in summer in our Country (Canada). There is more to contend with in several respects—such as bad light, too much moisture or frost, expense of heating and drying, difficulties in caring for materials. On the other hand a better grade of men can usually be obtained in the winter season; this is an advantage which almost makes up for the disadvantages, but not quite in my opinion.

A. E. CARTER.

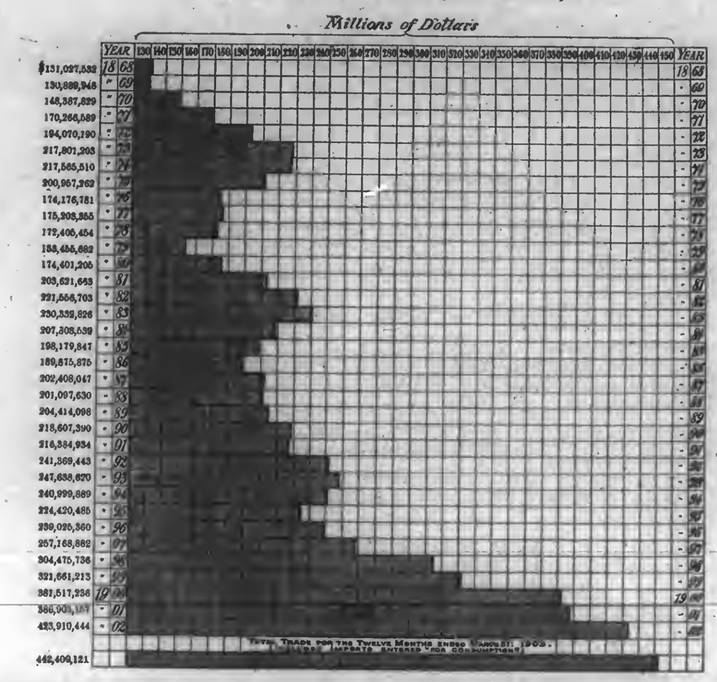
TORONTO, May 19th, 1903.

My opinion is that the inside work of an ordinary building, whether residential or commercial, cannot be executed more cheaply in winter than in summer. My reasons for this opinion are: 1st,-Artificial heat must be provided; 2nd,-Workmen always do more and better work in the bright days of summer than in the dull days of winter.

J. W. SIDDALL.

TOTAL TRADE OF THE DOMINION OF CANADA

FOR THE FISCAL YEARS ENDED JUNE 30TH, 1868 TO 1902.



PRACTICE.*

By R. M. Butler.

One of the first duties of an architect is to strive to administer his contract so that it may work out not only a substantial and creditable building, but that the contract may be carried out pleasantly and profitably to both parties to it. He should, so far as is consistent with his duties, aid in making the work reasonably profitable to the builder who has to earn his bread by such work. The architect must avoid being a partisan—above all should he disassociate himself from that class of employer to whom every builder is a rogue; he should if possible teach him better, or, if that be impossible, at least protect the builder. On the other hand, he must be prepared for the unscrupulous and dishonest builder and the builder who has a tendency to rush or curtail and cheapen work.

Then there is the tendency to accumulate extras from the day the first sod is dug. Builders who take work too cheaply are prone to encourage the young architect to make changes in his design, but if the practise is indulged in extras mount up and lead to friction in the end. Young architects must also be on their guard against becoming their employer's tool. He must be made to clearly understand that while every change does not necessarily mean an extra, it generally shapes that way. In a building of much artistic quality and detail changes are almost inevitable. The architect is not worth his salt who cannot improve upon his paper design, but in small or plain buildings there is less excuse for extras and alterations.

The two main causes of unpleasantness in building contracts are, first, extras and, secondly, cases where the builder is not made to clearly understand what it is he has contracted to do and finds later he has let himself in for more than he thought. This arises generally from his own stupidity or neglect, and sometimes from insufficiency and want of clearness in the quantities or in the plans and specification.

As to the first cause, we all know the insidious way in which extras arise. Frequently, in order to get a tender at a desired figure, the design is so cut down that extra items have to be inserted during progress, and this is scarcely calculated to please the employer.

One of the things which has most forcibly struck me is the unwillingness of many employers to frankly state the limit of cost they will go to. There are no bargains in building contracts. The full value must be paid if the work is to be sound. An architect is like a doctor; if the employer is to get the full benefit of the architect's services he must be perfectly frank with him; and it is the architect's business for his own protection, too, to keep him well up to this.

Having got so far, the architect's business is to keep the employer as free as possible of extras, of disputes, of law, and above all of so-called friendly arbitrations. My experience is that two actions at law are not so bad as one formal arbitration. Arbitrators seldom please either party: and if differences arise between the parties which cannot be settled by friendly give-and-take, or by the mediation or authority of the architect, let the issue be knit and tried by the best of all arbitrators—twelve jurymen, as I heard the late Judge Murphy say—or, what is even better, before an experienced, clear-headed and impartial judge. There is infinitely more chance in this of a satisfactory and equitable issue; but avoid law if you can.

Clear instructions having been obtained, let the plans and specification be plain and lucid, admitting of no misconception, accurate and workmanlike. If you have, for instance, an irregular and hilly site, let it be carefully levelled and the depths of the foundations at every point shown on the drawings; this is ever so much better than settling it when the trenches are opened, as is sometimes the case.

In the specification avoid conventional "padding" as much as possible. Let the work, however, be fully described in every detail, giving dimensions wherever possible. The most common faults in specifications are omissions. See that nothing, however unimportant, is left out.

Builders tendering are entitled to much consideration. They go to great trouble and expend much time in a labor for which only one can hope to be recompensed. Be scrupulous in such little matters as only opening the sealed detailed bills of men whose tenders are actually under consideration. Some builders don't care a jot about this, but others do.

Having secured a builder, the great thing is to be clear and thoroughly understood in all your drawings, details and instructions and orders of every kind. Let the last be as far as possible in writing. Order no important extra without acquainting the employer, for you are handling his money and pledging his credit.

Be careful when ordering extra foundations that you know what you want done and are getting no more and no less.

As regards clerk of works, I believe their utility to be enormously overrated. A good clerk of works is a jewel above price, and correspondingly rare. In great buildings of some intricacy, or in very remote places, a clerk of works is essential for administrative purposes and for working out troublesome problems on the spot; but in such cases he becomes really a conducting architect or architect-in-charge. The average clerk of works on an average medium-sized building is, I think, a useless luxury, and his wages might more profitably be spent upon the building itself.

I believe a downright dishonest builder is very rare—it is not to his interest in the long run; but against such a man the ordinary clerk of works is worse than useless, for his interference only incites foremen and puts them on their mettle to see how far they can fool him. I have seen many instances of this.

If you do have a clerk of works, insist upon his keeping very carefully and fully a diary, in which he enters everything of the least importance on the job, and, above all, insist on weekly reports—otherwise you are better off without a clerk of works. Do not allow him to get into the habit of ordering extras, however small The employer is not liable for such orders, but it is unpleasant to have to repudiate them.

In my own experience I have met with one, and only one, man who was really useful clerk of works and saved the architect much trouble.

I see by the address of the president of the Royal Institute of Architects of Ireland that the builders are pressing their case for a revision of the existing conditions of contract and that the two principal points are, first, the introduction of an independent architect in every building contract who shall be a sort of permanent arbitrator between builder and architect, and may be appealed to at any moment during the progress of the building to decide questions of materials, price, quantity and the intepretation of the plans and specification. I fail to see either the need or the equity of this, or how any architect would willingly submit to have his judgment daily and hourly questioned by a quarrelsome cantankerous builder. Even if the private architect yield to this, I think few corporations or public bodies will agree to this procedure. The other point is making the quantities part of the contract; with this also I disagree. That a builder should be compelled to do any work for which he is not to be paid, all because of the surveyor's error, is no doubt hard, but he takes the quantities at his own risk and it ought to be possible to devise some other safeguard, either by making surveyors guarantee their quantities or by some arrangement of independent checking. To say that an employer might at any moment during the progress of a building find his outlay compulsorily doubled would be an element about which there would be no finality, one which might lead to the employer's ruin, and would certainly tend to cripple and discourage building enterprise.

Both these proposals are, I think, clumsy and unworkable, and the builders have not proved the need for any such radical change in the whole principle of existing methods.

As to the architect's administration in general of the building. He should be possessed of sufficient legal knowledge to know how to act under all ordinary emergencies, such as the death, insanity or bankruptcy of the builder, the compulsory taking over of the work, dealing with refractory builders in regard to defective materials, and so on.

* Abstracted from a paper read before the Architectural Association of Ireland on December 16th, 1902.

PERFECT PLANNING.

Mr. Butler Wilson, in the address he delivered as President of the Leeds and Yorkshire Architectural Society, spoke of the hindrances which interfered with realization of perfect planning. Architects often have to deal with a site which bristled with obstacles and restrictions, and in such case it would be a fatal mistake to endeavour to place there a preconceived arrangement only suitable for some totally different situation. Rather should they endeavour to turn obstacles into advantages. Though they might have the desire to make themselves thorougly acquainted with the needs of the client, those endeavours were often met by ill-concealed indifference—an indifference which often expressed itself in some such words as "get the building finished, and we will adapt it to our requirements." But that was entirely unsatisfactory. Architects must be determined to fulfil requirements in a far more complete way than their clients had ever imagined.

Another difficulty was that of adapting the acknowledged forms of architecture to the ever-increasing advantage of modern constructive inventions. The fight between material and imagination did not decrease with the advance of time, and there was no doubt that many accepted forms were, under certain modern conditions, far from applicable to functions which this age demanded. To grapple with those demands and at the same time preserve the essential qualities of their art was the task which lay before them. This could best be done, not by ignoring or rejecting inventions and appliances which, on the grounds of their practical utility, had come to stay, but by a frank acknowledgement and acceptance of their value, and a determination to make those inventions their servants rather than their masters. They must be ready to progress in that respect, and to seize upon all that was best in modern constructional methods, for there was no law born of past experience which might not be instantly repealed owing to the appearance of new conditions and materials.

If architecture as a fine art was to live it must adapt itself to present needs. Iron and steel had almost ousted carpentry from buildings of any size, and the arrival of the flanged beam and iron joist marked a great era. Steel, combining as it did the virtues of cast and wrought iron, could be utilized for supporting enormous loads. The idea that constructive metal-work needed concealing from view was rapidly dying out. They were now able to build a partition 2½ in. thick which local authorities recognized as a 9 in. brick wall for fireproof purposes. Architects were, indeed, feeling the steady invasion of the technical constructor. Technical construction was advancing, and they must not allow the constructive specialist to gain an ascendancy.

THE QUALIFICATIONS FOR AN ARCHITECT.

These were summed up by Mr. G. S. Aitken in a recent address to the Northern Architectural Association as follows:—It is needful for the architect to be a man of culture, that he may have a mind open to all claims upon him and the best way to meet them. A man of taste, that he may do the right thing, whether in the use of form or the application of colour. A man of some degree of personality, that he may, avoiding the slavish copying of past work, give the world the best of his own. An alert man, ready to use the new inventions, taking care to do this with a well-balanced mind. An enthusiast, in favour of all that is good in the old, and yet looking forward to what may come, as well as backward to what has happened. A man in sympathy with the great students and thinkers who are able to influence his labour more than many seem to consider. One, thankful to all the great art writers who have worked in the right spirit, although he may not agree with all their conclusions. Seeing poetry in his art, that gives it proportion, grace, and lovely colour, as well as the prose that ensures stability of construction and consideration for the material needs of man. In sympathy with Nature if he would have his work full of perennial freshness, and seeking to become master in the knowledge of those principles by which through the Creator the world lives, moves, and has its being, so that they may have an influence on and find a place in the work he brings into existence.

The retirement is announced of Prof. William R. Ware, for twenty-two years professor of Architecture at Columbia University.

"If a doctor makes a mistake it is promptly put underground, but if the architect makes a mistake the building is forever staring him in the face. Let him spare no trouble, therefore, to make whatever is entrusted to him, no matter how small, as perfect as possible for its purpose, and as beautiful, regardless of whether it is going to pay him or not. Art in architecture consists in being simple and truthful. The ability of an architect is not determined by the amount of material he uses; one might almost say that as much ability is required to build a house as to erect a palace. Above all he should be ambitious, aim high, and he will hit the mark sooner or later."—Architecture.

SKETCHING IN CHARCOAL

Mr. Ralph Hedley, R. I. B. A., recently delivered an address on this subject before the Northern Architectural Association in which he said charcoal had been appreciated by artists for ages, but he did not think it had been quite sufficiently appreciated by architects. The reason why he advocated charcoal so much for drawing details of what ever kind of decoration was required was because it lends itself so readily to what one desires to express. Delicate, sharp or soft lines ; broad and delicate tints ; broad and decided shadows could be produced with charcoal with much more ease than with pen or pencil. With charcoal they could give all relative planes, of any required depth or strength, quality and feeling. That was of the utmost importance, and would enable details to be understood at once—that was projections and sinkings—if great care was taken to imagine a light coming from either the right or the left. In showing relief in a design, if they got the light full on it was rather deceptive when it was handed over to be executed. It was often very difficult to know whether the designer of some piece of ornament intended parts to be concave or convex without showing a section, and it was quite impossible to show sections in delicate parts of foliage. If a little thought was displayed in drawing, it could be expressed and understood almost as well as working from a model in relief. It was extremely difficult to express with pen or pencil in full-sized drawings. By the pressure required and the trouble involved in drawing a great number of thin lines all freedom was lost, and with freedom certainly individuality must be lost, and he thought every drawing of decoration should have individuality. The easiest way of getting individuality was by working with something that expressed thoughts, and they could not help themselves if they used charcoal freely. Their own feeling was bound to crop up.

PROFESSIONAL CHARGES.

The commission paid to architects will always be a subject of controversy until the meaning of a uniform scale is understood, says the Building News. Why every class of building, plain and ornamental, simple in plan and construction or complex, should be charged for at the same rate on the total cost it is difficult to say. The rate may vary in respect of the cost of the building—why not also according to the degree of complexity of design and skill required ? As the more complex the design the greater is the cost of construction, it follows that the professional services necessary may be valued in an inverse proportion to the skill and labour actually expended on the work. So it is, at least, in a very large number of cases which require not only a high professional skill and personal attention on the part of the architect, though the building may be comparatively small. Expenditure we know runs up on the plainest building when there is a large quantity of work or unskilled labour, as—say, in the construction of factories, sheds, workhouses, barracks, and other buildings, also in the multiplication of one design ; but the two kinds of cost must be kept separate. If it is fair to reduce the rate of percentage from 5 per cent. when the cost exceeds a certain sum for plain buildings, or for repetition of the same set of drawings, it is obviously equally unfair and unjust to expect the architect to design and personally superintend an elaborately-planned residence, hotel, or technical school at the same rate as he would ordinary dwellings or cottages. In other words, if he is expected to throw off 1 or 2 per cent. in any large buildings where there is great repetition or an enormons expenditure in foundations or brickwork, he is entitled to a higher rate per cent. upon those designs which are largely made up of fittings and decorations, the cost of which work does not exceed a certain sum. It seems absurd to fix a certain rate of 5 per centum as an arbitrary standard of remuneration unless we fix also the description and cost of the building which it represents.

SIZE OF WINDOWS IN RELATION TO FLOOR SPACE.

The following conclusions are the result of a careful enquiry recently made at Cornell University to determine the size of windows required to give an adequate supply of natural light to the lecture rooms between 8 a.m. and 5 p.m. All the rooms in question had unobstructed light :—

1. There is to be at least 150 ft. of window-space for each 1,000 sq. ft. of floor-space in rooms which, in use and location, are similar to those here described, and are lighted only from one side. Therefore an office 15 ft. by 25 ft. should have at least 56 sq. ft. of window space, and a class-room 30 ft. by 40 ft. should have at least 180 sq. ft. of unobstructed lighting surface.

2. The proportion between the height of the window-tops and the depth of the room lighted should be at least 500 to 1,000, or, in other words, the distance from the floor to the window-tops should be one-half the depth of the room to be lighted.

The American Architect observes that these figures support the old principle that "top-light" is the best ; the nearer the window-tops come to the ceiling the more efficient will be the lighting to be secured from a given surface. Care should be taken that overhanging lintels be not allowed to obstruct the light.

NOTES.

Mr. John Woodman, M. Can. Soc. C.E., formerly engineer of the western division of the C.P.R., has opened an office in the Merchants' Bank Building, Winnipeg, as consulting engineer and architect.

To complete the repairs of the Doge's Palace, Venice, it will probably be necessary to place beams across the canal over which the Bridge of Sighs is built, the beams resting on the wall of the prisons, to support the portion of the leaning wall fronting the canal.

Mr. Andrew Carnegie has offered to give unconditionally a million dollars for the erection in New York of a building to be used as the headquarters of the four great engineering societies of the United States and the Engineers' Club of New York.

The Western Architect is of the opinion that while concrete has been used for many purposes foolishly of late, as was inevitable, yet the building public have only fairly begun to understand its legitimate uses. While it is rapidly displacing stone for footing courses, its value as material for foundation walls, particularly in clay soils, has hardly occurred to builders generally. In these, careful excavation may be made, the earth making the outside of the mold for the concrete wall, which not only reduces the cost of planking below grade one-half, but lets the wall fill solidly against the earth, thus doing away with the annoying leaks that inevitably follow the laying of stone foundations in clay soils. Here concrete may displace stone walls, fewer cubic feet of materials producing far better results. Again, the Portland cement tile for floors has only begun its invasion of buildings.

ARCHITECTURAL COMPETITIONS IN BRITISH COLUMBIA.

An architect at Vancouver has sent us particulars of a competition for plans for a High School building to cost $70,000. The circular of conditions he characterizes as one of the most impudent productions he has ever seen. After describing the requirements of the proposed building, the circular concludes as follows :—"An estimate will be required as follows; viz. : for heating with steam direct, and indirect; hot water and hot air; the fan system to be adopted when heating by indirect steam and hot air. The entire cost of the building not to exceed the sum of $70,000 ; the architect to give a written guarantee to that effect. The following are the conditions upon which the plans are to be submitted; viz. : that all plans shall be the property of the Board, and that they shall have the right to use any portion of any plan or any ideas embodied therein. The Board will give prizes as follows : one of $75.00, one of $50.00 and one of $25.00. The architect whose plan is accepted shall not receive any prize, if he is retained to carry out the construction of the building."

What a rare bit of "nerve" is here exhibited by a body of men who, as our correspondent states, officially represent the education of the community! What a paradox to spend seventy thousand dollars for a building for the higher education of the rising generation, while at the same time asking a body of educated men of the present generation to give their services for nothing!

The young men and women for whom it is proposed to build this high school may be expected to question the wisdom of attending the institution if the knowledge they might gain would have no money value. From a money making standpoint they would do better to become day laborers or mechanics according to the implied standard of values of the representatives of education having charge of this competition.

It may safely be assumed, however, that if architects would hold their profession or calling in higher esteem, and show less anxiety to get work by any means and at any price they would not have made to them such absurd and insulting proposals as the one here referred to.

LEGAL.

An application having been made to the Irish Institute of Architects for information respecting the responsibility of an architect in connection with foundations, the hon. secretary was directed to reply that in the opinion of the Council it is not part of the recognised duty of an architect to sink trial pits to ascertain the nature of the ground upon which a building is to be erected, although in exceptional cases he may, if he thinks it advisable, recommend this to be done at the expense of the employer. The Council consider that the system universally adopted at present is equitable, as the employer only pays for the work which is actually executed. Summary statements of law, especially when formulated by laymen, are not always to be approved, says the Builders' Reporter, and there is a risk of the advice thus given being misunderstood. There are enough decisions to suggest that an architect is expected by English law to examine the site for a building or to have it examined for him, and he is liable for neglect if any damages should arise through acting on incorrect information. Although the builder is responsible for executing proper foundations, the architect is not in consequence exempted. If the builder should suffer loss he cannot look to the architect for compensation. In France the architect is liable to the client as well as to the contractor. Responsibility is believed to be evaded in England by avoiding to state the nature of the soil, either in a specification or on a drawing. But that is a doubtful expedient which has not been tested in the courts. The omission would be regarded with suspicion by judges. To ascertain the nature of the soil may sometimes be an expensive operation, in which case the advantage of making borings or trial pits should be explained to the building owner, and his sanction obtained for any necessary outlay. But in ordinary cases no architect who is careful of his reputation will neglect to ascertain the nature of the ground on which one of his buildings is to be erected.

NOTES.

The National Sculpture Society of New York, recently accepted for one of their exhibitions at Madison Square Gardens a piece of sculpture by Miss Florence E. Ward, of Toronto.

The special art scholarship of £60 given by the City Council of Liverpool through the Technical Instruction Committee has been awarded this year to Miss C. E. Martin, of the School of Architecture and Applied Art, University College, Liverpool. The scholarship is tenable for one year at London or some art centre on the Continent.

A French architect, M. Leon-Jean Roux, is said to have bequeathed to the Academie des Beaux-Arts a sum of 800,000 francs, or over £30,000 of English money. The income is to be applied to the creation of annual prizes in painting, sculpture, architecture, miniatures and illuminations, which will commemorate the names Destouches, Delarge and Roux. The academy already possess several funds for similar purposes, but the capital in each case was inferior to the amount bequeathed by M. Roux.

The director of works has decided to have the buildings of the Louisiana Purchase Exposition colored ivory white instead of old ivory white. Ivory white approximates very nearly the dead white which was used at Chicago on the Columbian Exposition. It has in it just a tinge of yellow. The departure from the dead white is expected to gratify the eye of the visitor, relieving somewhat the oppressive glare which characterized the Columbian Exposition during the sunny days. The departure from the white is not, however, sufficient to impair the majesty and dignity with which a great stretch of white facade impresses the spectator.

The Wesleyan chapel at Exeter will be the first large edifice in England erected by the Cottanein system, which has of late been quite extensively used on the continent. By this system, which originated in Fance, strength, durability, and also adaptability at moderate cost are secured by means of a skeleton of soft steel wire interwoven in the hollow of a special form of brick, or interlaced basket-fashion in varying thicknesses of cement. The building will have an inner and outer shell of three-inch brick covering a steel frame. The air-space between the two walls can be utilized for ventilation, and whereas the air-cushion will keep the interior cool in summer, it will also simplify the task of heating in winter. There is a further very important advantage in that the edifice will itself be fire-proof.

It has been proposed by certain foreign architects who practice in districts where great trouble is experienced from the destruction of brickwork by alkaline incrustations, to lay down a maximum limit for the presence of such impurities in bricks, and to reject all goods which show an excess over this limit. The amount of sulphur dioxides in a powdered sample brick is estimated, and a direct test for the influence of sulphates is also made, the bricks being treated in a vessel with a saturated solution of sodium sulphate by boiling for half an hour and then exposed to a current of air until an incrustation appears. This is repeated no fewer than forty times, after which the residue is dried at 1,000 deg. C. and weighed. The results, which are expressed in percentages of the original weight of the brick, give what is called the coefficient of susceptibility to attack by sulphates.

Choir screens originated from the stone balustrade or railings which separated the presbyterium from the other parts of the ancient basilica. They were afterwards retained to separate the space devoted to the clergy from that portion allotted to the congregation. Choir-screens were frequently of the most elaborate design, and were adorned with statues and traceried openings or panels. On the Continent many magnificent examples are to be found. The screen of the minster at Basle, that at Havelberg Cathedral, Munster, Germany ; and the Magdalene Church, Troyes, France, are splendid instances of choir-screens. In England we name Long Sutton, Kingsbury, Barnwell, Newark, Stanton Harcourt, and Chester Cathedral, in which churches the screen or rood-loft appears to have been used. The parclose screens at Fyfield (Berks), Ingham (Norfolk), Lavenham, Long Melford, Southwold, and Spalding, are good examples of wooden screens of the Perpendicular period.

TEST OF A CAST-IRON HEATING SURFACE IN CONNECTION WITH A FAN SYSTEM OF HEATING.

At the ninth annual meeting of the American Society of Heating and Ventilating Engineers a paper was read by Prof. R. C. Carpenter on a test made at Sibley College, Cornell University, of a cast-iron heating surface used in connection with a blower fan for heating the air. The data and record of the test in slightly condensed form reprinted from the Engineeridg Record, are given herewith: The heating system was arranged specially for the experiment by the American Radiator Company and consisted of twelve radiators placed side by side in two rows of six each, one row above the other and extending parallel to the flow of the air. Each radiator was composed of 21 sections, each of which was a single casting 9 x 36 inches, in the form of four nearly triangular tubes, slightly staggered, with half-inch air spaces between the tubes, all as shown in the accompanying sketch. Each section has a surface of 6.7 square feet giving a total for the whole heater of 1,692 square feet.

The fan drew the air over the heater and discharged it into a small chamber, to remove eddies, and thence through a delivery pipe and nozzle, where its velocity was measured, into the room. The fan used was made by the American Blower Company and was of the following dimensions: Height over all, 80 inches; diameter of wheel, 48 inches; width at periphery, 17.5 inches; inlet diameter, 30 inches; outlet, 27 x 27 inches. The fan was driven by a 6 x 6 inch vertical engine and was arranged to run at different speeds. The individual radiators were controlled independently so that it was possible to make tests with different amounts of heating surface.

The general results of the test are shown in the accompanying table, which contains a selection of eighteen runs from the twenty-eight as given with the report. Three runs at different speeds are given for each of the six different amounts of heating surface used, each amount representing a unit consisting of two superimposed radiators. The diagrams herewith show the relation between the speed of the fan and the pounds of steam condensed per hour for different amounts of heating surface; and the relation between the pounds of steam condensed per square foot of heating surface per hour and the cubic feet of air discharged per minute by the fan, for different amounts of heating surface. These curves show at a glance the proportionate decrease in the benefit derived as more heaters are added. In the discussion following the paper Prof. Carpenter stated tnat beyond 16 pipes, or in this case four heaters, the advantage gained was slight.

Three other diagrams presented with the paper but not given here, show the relation between the steam condensed for different speeds of the fan; the relation between the temperatures of the entering and discharge air; and the relation between the speed of the fan and the steam condensed per square foot of surface per hour, for different amounts of heating surface. The author was assisted in the test by Messrs. Neave and Cazenove, graduate students in the University.

DEMAND FOR ROOFING SLATES.

Mr. Harrison Watson, Curator of the Canadian section of the Imperial Institute, London, Eng., has written to the Department of Trade and Commerce at Ottawa, regarding a possible market for Canadian roofing slate. He says:

Quite recently a favorable opportunity for developing trade in an article which Canada possesses to a considerable degree has come to my notice. There is in the United Kingdom a very large consumption of roofing slates, many of which are imported. At a time when roofing slates were practically not used in the United States, the quality of slate deposits in that country was so suitable that several quarries were developed and worked solely for export purposes. In 1896 the slate trade with the United Kingdom amounted to some 46 million slates. Gradually, however, the utilization of roofing slates in building operations in America has been adopted, and between the domestic demands and the consequent increase in prices demanded by American slate producers, this export trade has steadily fallen away until at the present time it has almost ceased. Welsh slates, owing to labor troubles, have been also scarce, and United Kingdom buyers have been obliged to look temporarily to France for supplies. The French slate is inferior to American but is cheaper. A company which has developed and established the trade in American slates in Great Britain applied to me for information as to the possibilities of being able to secure suitable supplies from Canada. Upon inspection of a number of sambles of roofing slates from Canadian deposits, the expert informs me that the quality of the Canadian slate is very good and equal to, if not better than, the average American. The company, therefore, state that if they can arrange for regular supplies of the quality equal to that examined by them, they are prepared to contract for large quantities for which they would pay cash.

Provided that further investigation confirms the impression that large deposits of a suitable quality of roofing slate exist in Canada only awaiting development, the establishment of the industry would appear to offer a most profitable investment for capital which will, it is hoped, appeal to Canadian enterprise. The sizes most in demand here are 24" x 12", 22" x 12"; 22" x 11", 20" x 12", 20" x 10", 18" x 12", 18" x 10", 18" x 9", 16" x 12", 16" x 10"; 16" x 9", 16" x 8". They should measure 18 to 19 inches per 100 slates piled up in the flat. Quarrying is a fairly simple matter, the cost of the necessary equipment being less than in connection with most kinds of mining. As to labor, it is pointed out that a large number of experienced slate workers are at present idle owing to labor troubles in this country, and many would readily go to Canada for reasonable wages.

BY THE WAY.

Mr. Chas. Baillarge, the well known engineer and architect, of Quebec has had printed in pamphlet form his interesting paper presented recently before the Royal Society of Canada on "The Construction of an Indestructible Vessel fur a Voyage to the North Pole, and How to Reach it." Accompanying the paper is a map of the polar regions showing recent Arctic discoveries and plans for an indestructible vessel.

× × ×

Some of the ancient monuments in English cemeteries bear quaint epitaphs, complimentary and otherwise, to the departed. Here is one from a tombstone at Awliscombe, Devonshire:

"Here lie the remains of James Pady, Brickmaker,
late of this parish, in hopes that his clay may be
remoulded in a workmanlike manner
far superior to
his former perishable materials,—
Keep death and judgment always in your eye,
Or else the devil off with you will fly,
And in his kiln with brimstone ever fry,
If you neglect the narrow road to seek,
Christ will reject you, like a half-burnt brick."

NOTES.

So far as experimental results now available indicate it would appear that in order to attain impermeability in concrete, whether of gravel or of broken stone, that the mortar mixture must be at least as rich as 1 cement to 2 sand, or 1 cement to 2.5 sand, the proportion of mortar being sufficient to fill entirely the voids, or possibly a little more than that in order to provide for inequalities of mixing in different portions of the mass. Although apparently mortar of 1 cement to 3 sand has occasionally been found impermeable under as high pressure as 40 pounds per square inch, there is little evidence that such a mixture can in general be relied upon. In addition to the importance of these matters of composition to be employed for a permeable concrete, it is undoubtedly also of essential importance that the concrete should be kept thoroughly moistened during the entire period of setting; otherwise not only the ultimate resistance may be impaired, but also the impermeability by the slight contraction of setting in air which has been observed repeatedly. This has a marked influence upon the use of concrete in the walls of buildings, which in their subsequent experience may be exposed to driving rain storms, against which ordinary walls of masonry have frequently been found ineffective.

When an advertiser complains that his advertisement does not interest the readers of a paper, he might do better to change his ad writer than to change his paper. The public is anxious always to be interested, and if the advertisement fails to do it the fault probably lies with the advertisement and not with the public or the newspaper.—Printers' Ink.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO., of Toronto, Limited,
Publishers,
Confederation Life Building, - TORONTO, CANADA.
Telephone Main, 2362.

Branch Offices:
IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2699.
22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1903.

PRESIDENT - -	W. L. SYMONS, Toronto

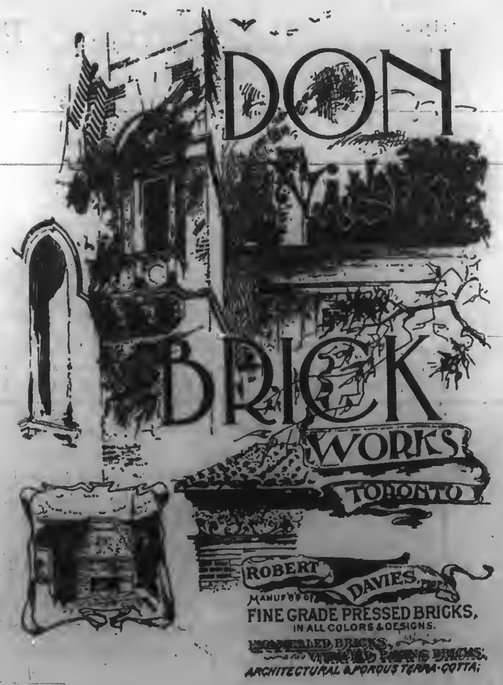
NOTES.

The tenders for certain work proposed to be done at Harbord street Collegiate Institute, Toronto, in comparison with tenders taken for similar work in 1898, were as follows:—

Plumbing	$1,685	$3,475
Masonry	382	1,800
Carpentering	365	707
Painting, etc.	90	129
	$2,632	$6,111



AN ARCHITECTURAL ALPHABET.

A was for architect, old in his prime,
B was a builder who took his own time.
C was a client who had his own views,
D was the details that no one would use.
E the erection he tried to excuse,
G was the ground plan exceeding the site,
H was the half-timber he had to reveal,
I was the ironwork he had to conceal.
J was the joinery, mostly of deal.
K was the king-post that ought to have stood,
L the stone lintel that proved to be wood.
M was the mullion that blocked out the light.
N was the newel too thin for its height.
O the oak sill that was not water-tight.
P was the price on the contract agreed,
Q was the quantities down to a bead.
R was the rage that the client displayed; and
S the sarcastic remarks that he made—when
T was the total that had to be paid.
U was the umpire called on to decide.
V was the value the client denied.
W stands for the words that he said,
X was the xtras for which he was bled,
Y Z the young zealot who wished he was dead.

You might as well try to conduct a business without advertising as to operate machinery without oil.—Printers' Ink.

"Book of 100 Stained Houses" is the title of a new publication by Mr. Samuel Cabot, of Boston. It contains illustrations of houses on which Cabot's creosote stains have been used and unsolicited testimonials as to their value.

Wallpaper of special design for the children's room continues to receive attention from the makers. A recent suggestion is wallpaper panels. They are about 12in. by 36in., and are shown in broad poster designs of life-size duck mothers leading a fuzzy yellow brood to a brook, fox terriers pursuing a red and black rooster, and apparently overtaking him, and processions of beggars coming to town. There are also posters of children going to bed, saying their prayers, eating their breakfasts, or playing. They are artistic, durable, and useful, as inculating a love of art and the beautiful.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingles stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

Stained woods and descriptive literature sent free upon request.

Estimates furnished upon application.

TERRA COTTA FIREPROOF BUILDING MATERIAL

POROUS TERRA COTTA among underwriters is classed as preferred risk, and the schedule of rates now enforced in the city of New York shows a difference, often great, which, computed means an annuity on large sums of money.

This indisputable fact appeals to architects as representing clients who may soon be exposed to the same classification in Canada. An apparent saving in selecting cheaper fireproof material may be more than lost through increased insurance cost.

POROUS TERRA COTTA FIREPROOFING is a credit to the buildings in which it is used and increases their selling value.

The **Montreal Terra Cotta Lumber Company,** Limited,
N. T. Gagnon, Selling Agent, 204 St. James St., Montreal, Canada.

A FIFTEEN-STOREY CONCRETE BUILDING.

A building fifteen storeys high, about 210 feet, in which concrete and steel will form the walls, is about to be erected in Cincinnati. The building inspector, who has to authorize the work, appears to have felt his responsibility in approving of the experiment, and an enquiry was held by him on the subject. It was explained that the concrete construction proposed was stronger and more rigid than steel, and will stand the vibrations and strains due to wind pressure better and in a more perfect way. The strength of the structure does not depend on rivetted joints, but on the monolithic character of the concrete, being all one solid mass of stone held together by twisted steel rods and imparting to it an elasticity equivalent to that of a steel building. The architects of the building are Messrs. A. O. Elzner & George M. Anderson, and the structure will be erected by the Cincinnati Fireproof Company. The building inspector of Philadelphia states that he has had a similar structure under his consideration, and that he had resolved to interpose no obstacle for its erection.

Composition capitals are now being used very largely in Canada. The Detroit Decorative Supply Company are large manufacturers of relief ornaments, staff work, architectural carving and modelling. Their exterior and interior composition ornaments are highly spoken of by architects and builders all over the Continent. The large works of this company turn out this class of goods in a particularly neat manner. They will be pleased to send their new illustrated catalogue to all mentioning this journal and addressing 812 14th avenue, Detroit, Mich.

A new building by-law adopted by the suburban municipality of St. Louis, near Montreal, provides that all new buildings on St. Lawrence street must be of pressed brick or stone and three storeys high at least; they are also to be built on the line of the street. It is expected that a regularity in design and construction will thus be brought about in the great number of business and residential buildings which are to be erected when the land for widening the street has been expropriated. In the new residential streets to be opened up the houses are to be built ten feet back from the line of the street.

New Process of ARTIFICIAL MARBLE
(In Keen's English Cement.)

I wish to lay before the public notice that I am now manufacturing Artificial Marble and that I have to that effect secured the services of Mr. Geo. F. Simpkin, who has had over 12 years experience with the leading firms of this special work in the United States and England. I am now prepared to undertake the manufacture of Artificial Marble Columns, Church Altars, Shrines, Bases, Capitals, Pilasters, (plain or fluted), Decorative Mantels, Dadoes, Pedestals, Etc. Samples of this work can be seen at my office or factory, 304 and 308 St. Joseph St., St. Roch, Quebec City, and at the Hochelaga Bank, M. S. Foley's Bellevue Apartments, Metcalf St., H. Morgan & Co., and Art Rooms, Philips Sq., Montreal.

Large Scale Parqueterie.

It is usual in England to floor the passages of a church with stone or tiles and the seating areas with wood, in the form of herring bone flooring, composed of pieces of unfinished wood about 4"x18." The size of the pieces is the principal part of the excellent appearance of this kind of flooring and the fibrous appearance of the unfinished surface is the rest. It is suggestive also, from the ease with which it can be repaired in parts, of suitability for a building where the flooring may be worn out in some spots sooner than in others.

Walls.

There is nothing in the way of railing so satisfactory as the stone baluster. The difficulty about it is its cost, for in order to give it its proper effect it must be used in stretches of some length. In London where, if there are, as it is said, 3,000 miles of streets there must be at least 300 of garden walling; a cement baluster and rails are extensively used on the top of a low brick wall plastered with cement. The effect redeems a very plain street from dullness, is not unmanageably expensive, and yet does not look cheap. One never sees a fence of this kind in a state of deterioration, so that there is no reason to suppose it is not durable; indeed the evidence of other work in the same material would go to promise a durability as great as that of stone. Sometimes the baluster and rails are of terra cotta. Both are apt to appear alike in time, because of the London leases which exact repainting every three years.

Insurance Against Strikes.

It is stated on authority of the President of the National Manufacturers' Association of the United States that a Mutual Company is to be formed with the effect of insuring employers of labor against losses occasioned by strikes. The company will also aim to protect independent workmen, by establishing a legal department and prosecuting persons who may attempt coercion or violate the law. It is proposed to keep secret the names of the members, so that when a strike is instituted it will not be known whether the fight is to be with an individual employer or a powerful organization of the character described. There is a movement all along the line to curb the powers of the unions to demoralize business and restrict the freedom of employers to employ whom they please and of workmen to sell their labor to whom and at whatever price they may choose. The general public are a unit with

the employers of labor in demanding that means shall be found to prevent the continued disturbance of commercial conditions and interference with individual rights. Legislation with this object has recently been introduced and is now being considered by the Parliament of Canada.

Building Restrictions.

As the result of a recent attempt to establish a factory in the centre of a choice residential section of Montreal, Alderman Vallieres has announced his intention to introdnce a by-law defining the limits within which factories may not be erected. Such a regulation should be inforce in every city, and ought properly to be incorporated in the building by-laws. There should also be a clear cut provision compelling property owners to keep their buildings back a certain distance from the street line. Numerous cases might be cited in which for want of such regulations heavy losses have been suffered by property owners in residential districts. It should not be possible for a factory, a livery stable or even the back premises of an apartment house to abut against residential property, nor for the house owner to build a porch or other projection so near the street line as to deprive his neighbor whose house is properly placed of the view up or down the street to which he is entitled. It is to be hoped that if the Toronto building by-laws supposed to be now in process of revision, ever reach completion, they will contain a clause which will properly regulate these important matters.

Old Mantles.

There is in England a trade in old mantels. When old houses are broken up, these, and no doubt other fragments of detail, are collected by dealers and sold for incorporation in modern work. The paint is cleaned off thoroughly, and in that state it can be seen exactly in what condition the work is. A correspondent in London who has been examining some of the stock at the warehouse of Thos. Hall, 25 Great Portland street, London, W., suggests that some of these mantels ought to be imported into Canada. The price ranges from about $30 to about $60. At that price they are cheap; and, with cost of importation added, would be still worth while for those who can afford to pay for a good thing. Though old, the mantels that are offered for sale are not shabby. They are usually of good design, which was the origin of their preservation, and are fully ornamented; and, whether because there is a softening effect of age or that the work is hand work, the ornament is more pleasing than in new productions of the same model. It would be possible for a purchaser to get sufficient description or illustration of some of these mantels to make up his mind as to their suitability.

Peasant Art.

There was recently held, at the Albert Hall in London, an exhibition of Home Arts and Industries, the annual work of a society which exists to foster the production of various forms of art in the leisure hours of working people. When the movement first began there was a tendency to claptrap: hammered brass and other forms of unmistakeable hand production, valued more for the evidence of handwork—what is known as "the loving marks of the hammer"—than for any real beauty. Now, however, there are some excellent productions in the way of homespun cloth and other textiles, lace, tapestry, pottery, cabinet making and wood carving. All these are good and useful productions; the country is better off and the people who make them are no doubt better off, both mentally and in pocket, for their production. But the interesting thing for a bystander is to observe that there is not a trace perceptible of variation from the ordinary types of similar work produced in the ordinary way. The cloth is simply good cloth; the lace is, to the eye of a male man, like other lace; the tapestry might have been designed, and perhaps was designed, by some one of the school of Burne Jones; the cabinet making might come from Grand Rapids, Mich.; the wood carving is as imitative of old work as is the best architect's; the pottery alone and some of the metal work had a noticeable note of freshness.

London Leases

The tenant in London assumes risks which would be declined in any other town. Houses are let under what is called a "repairing lease." "Reasonable wear and tear," which are excepted, in our leases, from the tenant's responsibility, are what, in London, the tenant has especially to make good. In other words the preservation of a man's property from the deteriorating effects of time depends not upon his own exertions but upon exertions which he exacts from the temporary occupant. The consequence is that there is always a floating valuation going on outside of the lease. An incoming tenant may have three money questions to consider: The rent, the repairs the landlord requires before he will give possession, and a premium to be paid the outgoing tenant for improvements effected by him—this latter in the case of taking up an unfinished lease, which often happens, for leases taken under these conditions are usually taken for as long as possible and are often transferred while still running. On the other hand, before a tenant quits possession, an inquisition is made by the agent of the landlord to see if the tenant is leaving the property in the condition in which it ought to be left; if not, an estimate is made of the necessary repairs, the sum is extracted from the outgoing and handed to the incoming tenant. It is probable that it would be more exact to say that the sum is allowed the incoming tenant and extracted from the outgoing tenant if possible.

One effect of shifting repairs from the owner to the tenant is that, even when a row of houses remains entirely in the hands of one proprietor, the repainting of the different houses is done at different times and a row is effectually relieved of monotony. The repetition of the original tint (usually a very light colour) in different degrees of freshness is rather an improvement to the look of the row, having all the pleasing effect of cloud shadows on a range of hills.

The most serious result to the tenant, of such a lease, is that the consequences of undermined foundations, earthquakes, windstorms, etc., fall on the tenant, who does not therefore feel in a sound position unless he has capital, beyond his needs, practically sufficient to rebuild the house.

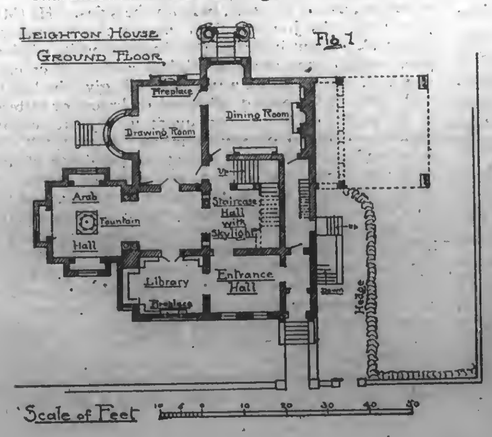
TOWER OF ST. PETER MANCROFT, NORWICH.
G. E. STREET, ARCHITECT.

NOTES ON TRAVEL.—II.

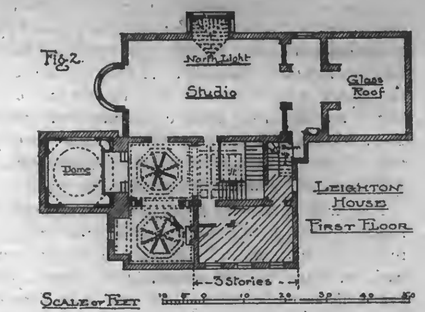
LEIGHTON HOUSE.

Lord Leighton's house has been pocured for the public by subscribers; and, under the management of a committee is open to the public. The floors are properly covered and there is a good deal of furniture but no knick-knackery. The walls are covered with chalk and pencil studies for his various paintings. These were also procured by the committee from Lord Leighton's heirs and elsewhere. They are well arranged in groups as pendants to a photograph of the painting which resulted from them, and form a valuable series of lessons in design for artists. But the house itself is the object of this study.

The house is designed for the interior. The exterior is not composed for display and would have little chance of being seen if it were. It is in the middle of Holland Park Lane, which is in reality a stable lane about 33 feet wide, with a cobbler's shop on one side of the entrance to it and the back of a livery stable on the other; one good house next to Lord Leighton's but retired in its grounds; a row of cottages opposite, two of which, as their signs declare, are inhabited by a clear starcher and a carpet sweeper; the rest of the lane occupied by studios of a modest kind, some of which are converted stables, and by stables which are still unconverted and in the gall of bitterness.

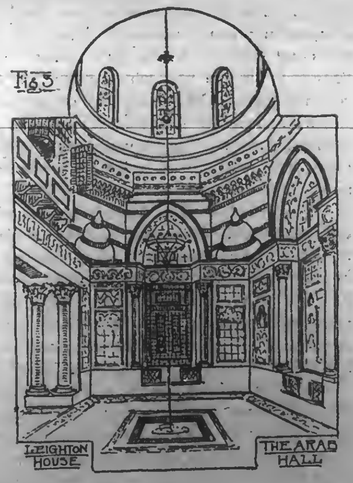


Once in the house there is no occasion to think of the approach, which is indeed partly justified already by its quietness. In London it is only necessary to be one remove from the traffic of a main artery in order to be quiet. There is no roaring trolley or ringing asphalt; the pavement is of square wooden blocks on concrete, and the intervention of a garden is enough to make its soft roar sufficiently remote. The front of Leighton House is desirably quiet and the rooms looking upon the garden behind, upon the north side of the house, are a model of peace and dignity.



The house is distinctly a house for entertainment. Lord Leighton was unmarried and lived alone. His bed room was in the shaded portion of the upper floor. This area is now set apart for the office of the honourary secretary of the committee and is not open to the public, but, from its shape and the arrangement of the doors it seems probable that the bedroom was the larger square to the east and that the smaller square beside it was a dressing room or bathroom.

The kitchen was in the basement, as is usual in London, and the servant's bedrooms on the third floor, over Lord Leighton's own bed room.



The special feature of the house is the Arab Hall. It is of course an exotic: the latticed windows are not needed to exclude the already subdued light of London, nor is the air so parched that a fountain is a first consideration for luxury; but, like many other exotics, it has a special charm from being a remove from the

ordinary. The real charm is however its perfection, the work, at the bottom, of the architect, Mr. Arichison. It is the proportion and balance of the design which are the real base of the beauty which the enamelled oriental tiles decorate ; but, together, they make a piece of work which seems to lack nothing of perfection. To sit in one of the wide window seats and let the eye rest on the harmony of the design while the ear enjoys the music of the fountain echoing in the dome is to enjoy perhaps as distinct pleasure as mere architecture can give.

There is no photogragp procurable of this hall, or indeed of any part of the house ; and in any case a photograph could not take in the upper part of the hall, which is included by the eye. A drawing may be made to suggest a little more in this respect but can do almost nothing in the hands of an unskilled draughtsman, towards giving an account of the elaborate decoration of the surface, even as regards the lines, and nothing at all to suggest its colour.

The Arab Hall is 17 feet square. The floor is of mosaic marble with a border of coloured scroll work round the edge and a black marble border round a basin of water, 5 feet square, in the centre, which, below the surface of the water is sunk in the form of an octagon with angles centered on the sides of the basin, and a semicircular sinking springing from each side of the octagon and about half a side in diameter. A pipe nozzle, projecting above the surface of the water, at the centre, sends up a stream, of about 1/16 inch in diameter, about 3 feet high. This falls back into the basin with a musical sound to which the echoing character of the hall largely contributes. The walls have a black marble dado up to the window sills, 2' 6" high. The windows are covered by lattices of Mashrabeeyeh work. The window bays are 9 feet wide by three feet deep, with angle columns of white marble (incorrectly shown in the plan as projecting into the recess). The column recesses are lined with light coloured marble an inch thick. The outer edges of the slabs are flush with the wall surfaces and form a boundary for the tiles which cover the walls. The columns have alabaster capitals carved with storks, which are reversed on adjacent sides and make symmetrical forms. The columns carry a flush frieze, about 2 feet deep, with a mosaic scroll, having birds and animals for the details. This frieze runs across the windows also. The frieze is finished with a 6 inch cove and fillet, with about half-inch projection from the frieze and quirked at the top of the cove. The wall spaces from dado to frieze between the columns is covered with old tiles, mostly of the 16th century, procured in Rhodes, Cairo and Damascus on different occasions. They may all be described as a rich blue and white. The blue has that mingling of green which is usual in oriental work. The tiles came from different places and are probably the work of different generations ; each portion of wall has at least two subdivisions of pattern, and no two portions of wall are alike ; but the harmony both of design and colour is perfect. The windows have pointed arches faced with dark marble, moulded : the soffits are mosaic, similar to the frieze. From the frieze spring squinches, if they can be so called, like inverse and inverted pendentives, with a delicate outline of many curves which carry a truncation of the hall with great neatness. The truncation is further extended by a complicated Arab cornice, of many ogee arched projections, until they become side of an octagon upon which the dome sits. This part of the wall is all in porcelain or enamelled tile ; white, with wide blue bands which cross the squinch forms so as to exhibit their modelling. The dome has moulding in colour at the bottom, a dull gold or yellow surface and eight circular headed lights filled with genuine Persian coloured glass, very deep in colour. Over the frieze where it crosses the entrance to the hall (a marble beam on columns) is one of those projecting lattice windows, a piece of old work, brought from the east. This looks into the hall from the hall in the first floor.

A description of the Arab Hall would be incomplete without some notice of the value which the unlighted middle hall gives to both this and the well lighted staircase.

W. A. LANGTON.

(To be continued.)

BY THE WAY.

The field is already so full of specialists and so-called experts that the functions which ought to belong to and discharged by the architect, are becoming less and less clearly defined. Yet there is apparently a disposition to specialize still further. The recommendation has recently been made that service of the "lighting engineer" should be procured to determine the character and location of lighting fixtures which should be employed in a building, their effect upon the decorations, color of light to harmonize with fittings, disposition of occupants of rooms and character of employmen therein, expense of installation and maintenance, burners available and supplies or repairs for the same, etc., etc, Now if the architect who plans a general scheme be not competent to deal with the details thereof, it seems to me he had better abdicate entirely, and hand over the whole business to the "specialists." Within proper limits the latter are doubtless a distinct aid to the architect, but if success is to crown the work, there must not only be expert knowledge in the various departments, but also a master mind to plan, supervise and harmonize the whole undertaking.

× × ×

According to the Meriden Journal, M. M. Jones, (nothing extraordinary about the name) an architect of that city, has invented a measuring rule that may almost be said to be capable of measuring anything, anywhere, and of any size, beneath the skies. He (Mr. Jones) says the Journal: Has taken a cheap, common rule, and, without increasing or diminishing its original size, weight, appearance or original usefulness or convenience, has produced a rule that will give the length and levels of the ends of all kinds of braces or rafters. It will square off a board or square and lay out a cellar, make an octagon or square mitre. It will tell the height of any building or elevation, the depth of any valley or chasm, the width of any street or stream, or both. Anchor a boat in the middle of a river, and the rule will tell how far it is from shore ; a roofer can tell the dimensions of any roof while standing on the ground ; it will measure anything in sight, whether in reach or not ; it will give the length of any straight or slanting line, it solves all the problems in geometry and trigonometry the mechanic is ever called upon to solve. The improvement can be attached to all kinds of rules in use, whether of the French or English systems, and to a new rule while making. One cent per rule will pay the cost of the improvements ; to a rule already made it will cost two cents a rule.

THE NATIONAL ASSOCIATION OF MASTER PLUMBERS, STEAM AND HOT WATER FITTERS OF CANADA.

The eighth annual convention of the above Association opened in Forester's Hall, 505 Craig Street, Montreal, on the 2nd of July, The President, Mr. F. Powers, presiding. The president in his annual address stated that the relations of the master plumbers with the manufacturers and supply firms were of a friendly, and on the whole, satisfactory character. The membership of the Provincial Associations was steadily increasing. New associations have been organized during the year at Sydney, and on the Island of Cape Breton. Attention was called to the necessity for the appointment of a permanent secretary and organizer to be paid a salary sufficient to enable him to devote his whole time to organizing and association business. Owing to the shortening of credits to 30 days by the manufacturing and supply firms, it was recommended that the plumbers also curtail credits to thirty days.

The report of Mr. Peter C. Ogilvie, vice-president, contained the following suggestion: "I think that in the interest of every one, no contractor should make a contract with any labor union, until such time as they become incorporated bodies. As it is now, a contract is only kept until such time as it suits them best to break it ; I sincerely hope that we will be able to get some practical suggestions from some of those present at this convention."

Mr. W. H. Meredith, vice-president for Ontario, urged the importance of organizing associations for every province, and as a proof of the advantage of so doing, referred to the fact that all the principal towns and cities in Ontario now had local associations, and that in Toronto 95 per cent. of the master plumbers are members of the local association.

Mr. James Farquhar, vice-president for Nova Scotia, referred to the fact that the Board of Health at Halifax is very strict in the enforcement of sanitary regulations, and that there is co-operation between the Board and the local plumbers' association in behalf of the enforcement of sanitary laws.

The President of the Montreal Association, Mr. T. O'Connell, referred in his report to the good feeling existing between the Master Plumbers' Association of Montreal, and the local Journeymen's Union. Reference was also made to the fact that the city plumbing by-law has been amended in several important particulars, one of which was that journeymen have now to undergo examination.

George A. Perrier, secretary, in his report also referred to the necessity for the appointment of a paid secretary who should reside at a central point, and be in a position to have at all times a thorough grasp of the affairs of the Association.

The President called attention to an Act passed by the Legislature of the State of New York and which is now in operation, having reference to government and municipal contracts. This Act had been revised with a view to its presentation to the Dominion government for adoption, and is as follows :

The people of the Dominion of Canada represented, do enact as follows :

Section 1. All specifications or contracts hereafter made or awarded by the Dominion, or by any public department or official thereof, for the erection and construction of buildings, shall be understood to embrace stone and mason work, carpenter work, painting and decorating work, plumbing, heating, electrical work, structural iron work, and roofing.

Section 2. The officer, board or commission charged with the duty of drawing specifications and contracts for the erection and construction of buildings for the Dominion, or any political or other sub-division of the Dominion, must draw separate specifications and contracts to cover the separate kinds of work referred to in Section 1 of this act, and they must be so drawn as to permit of unfettered bidding for and upon the separate branches of work to be performed.

Section 3. All contracts hereafter made or awarded by the Dominion, or public department or official thereof, for the erection and construction of buildings, are to be awarded separately upon the separate branches of work, as referred to in Section 1 of this act, to responsible and reliable individuals, firms and corporations engaged in the business of the kind to which the work to be performed belongs.

Section 4. No bid shall be received or accepted by the Dominion or any public department or official thereof, unless the party making the bid shows by affidavit that he is a citizen of the Dominion of Canada, and as a test of his fitness to properly perform the work bid for, that he has served an apprenticeship of at least three years at the line of work specified in his bid, or that he is a contractor in the particular line, and has had at least five years' practical experience.

Section 5. If any person, firm or corporation, to whom any contract is hereafter let, granted or awarded, by the Dominion or by any public department or official thereof, shall, without the previous written consent specified in Section 5 of this act, assign, transfer, sublet or otherwise dispose of the same, or any right, title or interest therein, to any other person, firm or corporation, the Dominion, public department or official thereof, as the case may be, shall be relieved and discharged from any and all liability and obligations growing out of said contract, and to the persons, firm, or corporation to whom be shall assign, transfer or sublet, or otherwise dispose of any right, title or interest in the same, and said contractor, and his assignee, transferee, or sub-lessee shall forfeit and lose all moneys theretofore earned under said contract, except so much as may be required, to pay his employes, provided that nothing herein contained shall be construed to hinder, prevent or affect an assignment by such contractor for the benefit of his creditors, made pursuant to the Statutes of the Dominion.

Section 6. All acts and parts of acts inconsistent with this act are hereby repealed.

Section 7. This act shall take effect immediately.

The proposed measure met with general approval, and a committee consisting of the President, past-president McKinley and the treasurer, Mr. Lamarche, was appointed to interview the Minister of Public Works

and the Ministers of all spending departments of the Government and urge upon them and upon the Government the adoption of this measure during the present session of Parliament.

The action of the manufacturers of soil pipe and fittings in deciding to discontinue, after the 1st of January next, the sale of light soil pipe and fittings, was endorsed.

The Committee on Resolutions suggested that clause 1 of the President's report be amended to read as follows: "That it be a recommendation from the National Association, that any agreement which local associations may make with the journeymen, should be ratified by the International Association of Journeymen Plumbers." On recommendation of the committee the other reports were adopted. The committee recommended that the revenue of the Association be enlarged by an increased per capita tax, thus placing sufficient funds at the disposal of the officers of the Association to properly prosecute the work.

The Executive Committee were instructed to place themselves in communication with the National Association of the United States to learn if it would be agreeable to that organization to have a representative of the Canadian Association attend its next annual meeting and to reciprocate by sending a representative to future annual conventions of the Canadian Association.

It was decided by vote that the next convention of the Association should be held in Toronto commencing on Wednesday, July 20th, 1904.

The following officers were elected for the ensuing year: President, Joseph Thibeault, Montreal; Vice-President, Robert Ross, Toronto; Secretary, H. A. Knox, Ottawa; Treasurer, F. G. Johnson, Ottawa. Provincial Vice-Presidents: British Columbia, John McKinley, Ottawa; Manitoba, A. J. Hammond, Winnipeg; Ontario, H. Mahoney, Guelph; Quebec, Joseph Lamarche, Montreal; New Brunswick, W. Watson, Moncton; Nova Scotia, Geo. Kinsman, Halifax. Chairmen Standing Committees: Legislation, E. B. Butterworth, Ottawa; Apprenticeship, G. A. Perrier, Halifax; Sanitary, James Hughes, Montreal; Essay, John Watson, Montreal.

A conference was held with representatives of a number of manufacturing and supply firms, when trade relations were considered. The plumbers pointed out the desirability of a Dominion organization of manufacturers and dealers in plumbers' supplies, so that trade differences might more easily be discussed and remedied. At a subsequent meeting of the manufacturers and supply firms it was decided to form such an organization.

A very enjoyable evening was spent in connection with the Annual Association Dinner held at the Windsor Hotel. In the unavoidable absence of Mr. Thomas O'Connell, President of the Montreal Association, the chair was occupied by Mr. Lamarche, having on his right the President of the Association and on his left Mr. J. S. Archibald, Vice-president of the Province of Quebec Association of Architects. The toast of "The National Association" followed the toast to "The King." It was proposed by Mr. P. C. Ogilvie, and responded to by the President, Mr. Powers. The President of the Toronto Association, Mr. R. Ross, proposed the toast to "The Montreal Association." Messrs. Joseph Laurier and Mr. Lamarche made suitable replies. Mr. W. H. Meredith proposed the toast to the "Invited Guests," which he said included the architect, the manufacturer and the journeyman. Mr. Mr. J. S. Archibald, Vice-President of the Province of Quebec Association of Architects, extended the hearty felicitations of that organization to the Master Plumbers' Association, and congratulated the latter upon the scope and usefulness of its work. Replies were also made by Mr. Howard, President of the Journeymen's Association, F. J. Travers, Peter McMichael, S. R. Brewer, A. D. McArthur, Alex. Robertson and J. L. F. Carron on behalf of the manufacturers. The toast of "The Ladies" was proposed in felicitious terms by Mr. Fred. Armstrong, of Toronto, and replied to by Mr. Harry Mahoney, of Guelph.

FALLACIOUS CEMENT TESTS.

Mr. D. B. Butler, Vice-President of the Society of Engineers of Great Britain recently read a paper before that body on the above subject, in which he referred to the uselessness of many of the tests now employed. In conclusion he stated that whilst recognizing the fact that exceptional circumstances require exceptional qualities of cement, he submitted the following standard specification as one which would ensure the delivery of a good sound cement suitable for the requirements of general engineering constructional work.

The whole of the cement shall be pure Portland cement, and shall conform to the following tests:

Fineness of Grinding.—To be such that when sifted through a standard sieve having 50 holes per lineal inch there shall not be more than one-half (½ per cent.) by weight of residue; when sifted through a sieve having 76 holes per lineal inch, there shall not be more than five (5 per cent.) of residue; and when sifted through a sieve having 100 holes per lineal inch, there shall not be more than 12 (12 per cent) of residue.

Time of Set.—A pat of neat cement gauged with the minimum of water at the normal temperature (60 deg. F.), and placed on a glass or other non-porous slab, shall not commence to set in less than eight minutes, or take longer than five hours to set hard.

Soundness, or Freedom From Expansion and Contraction.—A pat submitted to moist heat and warm water in the Faija apparatus for soundness at the usual temperatures—viz., 110deg. F. and 120deg. F. respectively, shall show no cracks or signs of expansion after 24 hours.

Tensile Strength. — Briquettes of neat cement, gauged with the minimum of water on a non-porous bed and placed in water 24 hours after gauging, shall carry an average tensile strain of not less than 350 lb. per square inch after three days, 450 lb. after seven days, and 550 lb. after 28 days from the time of gauging. Briquettes composed of three parts of standard sand to one part of cement by weight, treated as above, shall carry an average tensile strain of not less than 150 lb. per square inch at seven days and 250 lb. at 28 days from the time of gauging; but no matter how much greater strength may be developed at the earlier dates, both neat and sand briquettes must develop an increase of at least 50 lb. between each date.

Building operations in Vancouver, B. C., have been retarded by a strike for an 8 hour day of workmen in the sash and door factories.

New Street Entrance to City Arcades, Birmingham.

BUILDING MATERIALS AT THE LONDON BUILDING TRADES EXHIBITION.

Our representative in charge of our British office, 22 Great St. Helens, London, E.C., has sent us particulars of some of the exhibits of building materials and appliances shown at the Building Trades Exhibition held in London last month. Out of the large number of exhibits have been selected for mention those which were thought to be adapted for use in Canada and which might therefore be supposed to have an interest for the readers of this Journal. In interviews with the firms whose exhibits are mentioned below, our representative learned that it is their desire to obtain suitable agents in Canada with whose assistance they might be enabled to place their goods on the Canadian market and make their merits known in this country. The firms in question are of first-class standing, and manufacturers' agents in this country would do well to open correspondence with them. By so doing, either direct or through our London office, they would be assisting the present movement for closer trade relations with Great Britain and at the same time would no doubt establish for themselves profitable business connections.

Mellowes & Company, Limited, Corporation street, Sheffield.—This exhibit consists of a wooden structure entirely glazed on Mellowes' patent "Eclipse" system. The bars which support the glass consist of a steel bar entirely encased in a tin lead cover,

having webs on either side, which are rubbed down on to the glass (see sketch). Contraction and expansion are amply allowed for. No paint or asbestos is required, and no maintenance is necessary. It was learned that the glazing has been in use for 22 years, and is absolutely waterproof.

The Newellite Glass Tile Company, Limited, 139 Cannon street, London, E. C., exhibited their glass tiles, a perfect wall lining, with a clean impervious surface, unaffected by frost or weather, and absolutely free from the defect known as surface cracking or crazing. The nature of the key is a matter of the greatest moment, and if the tile is to be relied on, this key must be elastic, because the glass expands and contracts much more than the cement on which it is fixed. They claim the key of the "Newellite" Tile is of this elastic nature, enabling the glass to yield to the action of the cement to which it is affixed, while at the same time most firmly secured. The company are prepared to accept orders under the most exacting guarantee of durability, or on contracts of approved magnitude they will agree to a 10 per cent. retention for a period of two years from the completion of the work.

The stone exhibited by Messrs. Mackay & Davies, Cardiff, is known as the Blue Pennant. It is of a deep blue color and well adapted to all kinds of engineering, architectural, and surveyors' work on account of its even grain, exceptional solidity and great resistance to crushing. As regards weathering properties, it is very hard and durable and is largely used and highly spoken of for curbing, channelling and paving purposes. It can be supplied in large blocks sawn for steps, landings, sills, etc. The specific purity of the stone is 2.68 and percentage of water absorbed after 24 hours immersion is only 0.28.

The exhibit of Messrs. Josepb Place & Sons, Limited, Darwen, consisted of white, colored and salt enamelled bricks. The white glazed bricks have a heavy glaze with a perfectly even surface and are in this respect specially noticeable. The colors are in great variety, every shade of color being exhibited and it is now possible to match almost any color that may be desired. The salt glazed bricks are especially noticeable because of the richness of the glaze and the uniformity of the coloring; these salt glazed bricks have now reached an excellence of quality which is seriously affecting the enamelled brick trade, and, which produce a wall having variety without shadiness as compared with the flat uniformity of enamelled bricks.

The Velvril Company, Limited, 29 New Bridge street, London, E. C., made an exhibit of Velvril paint which is said to contain no lead or linseed oil; it is supplied ready for use, is easy to work, quick drying, gives a smooth hard surface, is not affected by atmospheric influence, is elastic, durable, does not fade or blister, and is perfectly waterproof and non-corrosive. It is suitable for use on iron, steel, wood, cement, etc., also for all kinds of decorative work. Velvril priming paints and varnishes are specially prepared for use with the paint. The company would be pleased to receive applications for the Canadian agency.

Major & Company, Sculcoates, Hull, exhibit the effects of their wood preserving stain "Solignum" in a most effective manner. Their stall consisted of a model half timber house in an enclosure, a railing and gate in front separating it from the gangway. All the half timber work of the house was treated with the medium and dark shades of Selignum, and looked very well, these two shades being most suitable for this class of work. To exemplify its effect as a preservative, three post ends were exhibited which had been buried in the ground for four years. The post ends untreated with Solignum shows considerable rotting, whereas those treated with one and two coats were perfectly sound. Though largely used on all kinds of woodwork in England, there is believed to be still wider scope for Solignum in the colonies and other countries where timber buildings are more in vogue and where in consequence of the severe climatic conditions wood is more liable to perish. It is being used in South Africa and Australasia in ever increasing quantities and with great satisfaction. It renders wood impervious to the attack of the white ant, and is a reliable preventative against dry rot. There should be a great future for Solignum in Canada.

Messrs. Sissons Bros. & Company, Limited, Hull, showed on a screen some charming examples of wall decoration in Hall's washable distemper in conjunction with their white Japan paint. In these schemes of decoration the colors are of the utmost delicacy and bear ample testimony to the value of the distemper as a decorative material, to say nothing of its hygienic qualities, which are of course obvious. It is perhaps necessary to say that the distemper can be had in any color.

Newell Bros., 192 Grosvenor Terrace, Camberwell, London, S. E., showed specimens of their tiles and sanitary wall linings, including the opal glass tiles for which are claimed, as specialities, super-

tor thickness, permanent white backing, and ease of fixing. Mr. J. T. Newell the pateotee, is one of the pioneers of the glass tile trade, and has produced the opal glass tiles as a result of long and careful study. The firm, who are contractors to H. M. Government and the principal hospitals, handle all kinds of sanitary ware and hospital fittings, and specialize on thick opal white microbe proof wall linings and slabs. Newell Bros. have a large export glass tile trade, and are selling in millions a very cheap and good glass tile.

Stanley Bros., Limited, Nuneaton, had on exhibition the following list of goods manufactured by them: Glazed bricks—brown, grey, granite, white and coloured; glazed sinks, brown and amber; glazed socket pipes and connections; terra cotta, red and buff; chimney pots—red, buff and salt glazed; roofing tiles—plain and ornamental; semi-encaustic paving tiles—plain and ornamental; red and blue ridges, finials and ventilators; blue pressed bricks, copings, garden tiles, and ventilating bricks; red, blue and buff Staffordshire quarries, glazed and unglazed malt kiln tiles; stoneware conduits, troughing, etc.

The Cloisonne Glass Co., 66 Berners St., Oxford St., London, W. The manufacture is called "Cloisonne Glass" and we cannot do better than quote the description of the inventors, and the logic of its name "Cloisonne." On a plate of glass of any texture or colour, the design is executed in thin metal strips or cloisons in precisely the same manner as in the older industry, but in the latter case a copper plate was used as the foundation upon which the strips were arranged. The design having wrought out to the required point, the cloisons are permanently cemented in place. The spaces between the cloisons are then filled in with small particles of glass of different textures or colours to carry out the design. The whole is then cemented to the transparent backing by a translucent material; a second sheet of glass is hermetically cemented over the work, and neither temperatures, nor climatic influences can affect it further. Most artistic effects are thus produced, the colours being radiant with light and valuable when seen through or when looking upon them. Portions of the glasses may be left clear and thus a beautiful contrast effected.

E. Turner & Sons, Penarth Road, Cardiff, exhibited samples of the different stones they quarry, namely, grey and blue Forest of Dean stone, Tintern Abbey stone, Farleigh bed bathstone, Corsham bed bathstone, Corngrit bed bathstone, also the red St. Bees stone, for which they are agents.

Darwen Sanitary Pipes Limited, Darwen, Lan., exhibited samples of large pipes, consisting of 36", 30" and 24" diameter sanitary tubes in 3 ft. lengths, also sample of an ordinary 18"/6" street gullies 4 ft. deep, and samples of special channel interceptors, and yard gullies. This firm make a specialty of pipes of large diameter, and their works are exceedingly well equipped for turning them out in large quantities and first-class quality, their raw material being most suitable for 21" pipes to 36" diameter.

F. McNeil & Co., Lambs Passage, Bunhill Row, London, E.C., exhibited asphaltic roofing felt for exterior roofing, bituminous or inodorous felt and sarking felt for lining slate, tile and metal roof, and for lining corrugated iron buildings.

Colledge & Bridgen, Wolverhampton, are sole licencees and manufacturers of Fisher's patent window attachment which has been designed with the object of preventing the numerous accidents frequently occurring when cleaning widows from the outside. Fisher's patent fittings are neat, easily fixed and cheap, and can be applied to new or old sashes. They allow the sashes to slide up and down in the usual way, and also to be opened into the room for cleaning and other purposes.

Messrs. B. & S. Massey, Openshaw, Manchester, exhibited an extremely useful drawing desk for the especial use of architects and other draughtsmen. The board is so constructed as to allow the user to keep in a perfectly upright position or adjust the desk to meet his own wishes. The table which is part of the outfit is constructed to hold conveniently any designs the architect may have or whatever size they may be. The whole apparatus is handy, neat looking and should be a useful adjunct to a designer's office.

The Marmorite Artistique Syndicate, Ltd., 154 and 155 Salisbury House, London Wall, E. C.—This firm's exhibit of Marmorite was much admired at the Building Trades Exhibition. The material is a splendid substitute for marble, can be made to any design and in any colour; and is specially suitable tor public or private buildings, luocheon rooms, lavatories, advertisement tablets, shop-fronts, etc.

The Crystalline Co., Ltd., The Platts, Stourbridge, exhibited snow white, opaque colored, porcelain opal, overglaze, and semi transparent tiles—A new product manufactured from porcelain opal with a "grip" or "key" back to enable it to adhere perfectly to cement.

An effective exhibition of "Mezotil" a new and attractive mural decoratioo, was shown by the London Tablet Co., of Sydenham, whose proud boast it is that their product is the result of a combination exclusively Englisb, namely, that it is made in England with English capital and by English labour. This wall covering consists of sheets of zinc of the normal size of 3 x 2 feet, enamelled and decorated in various styles, the designs hitherto employed being chiefly in imitation of tiles. As a clean, bright and inexpensive wall decoration this material deserves more than cursory attention. It is of course non-absorbent and vermin-proof.

The Permanent Decorative Glass Co., Lancaster, Manchester, and at 36 Basinghall St., London, E. C., exhibited examples of their well-known "Finrite Opal" tiling and metal wall decorations, including a large variety of pattern tiles, imitation marbles, granites, ornamental borders, &c. They had also a tiled partition showing several excellent examples of their work. The advertisement of this company will be found in the British section of this paper.

Mr. W. E. Farrer, Cannon street, Birmingham, exhibited an automatic alternative distributing apparatus for small bacteria beds, such as are required for use for large public buildings, as asylums, isolation hospitals, barracks, &c. Distribution is provided for by means of an automatic tipper discharging alternately into two sets of light perforated cast-iron channels supported about 1 inch above the filtering medium. Torfit urinals, by the use of which flushing is rendered unnecessary; an improved apparatus for flushing sewers, closets, etc.; a patent lattice-gear penstock or sewerage valve, a rust-collecting chamber for the base of sewer ventilating columns, &c.; and a selection of his sluice, air and other valves were also shown.

Messrs. Mather & Platt, Salford, exhibited a model of their automatic mechanical sewage distributor which, according to the analytical report by Inspector Leigh, gives admirable results. A model may be seen here of their patent gravity filter, which consists of a large circular iron tank, open at the top, and resting on a cast-iron chamber in which the filtered water collects before its discharge through the outlet-valve. The collecting-chamber is separated from the filtering-tank by a dished iron plate into which a large number of brass nozzles of special design are screwed, the object of which is to insure the effective use of all parts of the quartz bed during filtration, and a proper distribution of the water used for washing out. On this plate rests the quartz bed in graded layers, passing from the coarsest at the bottom to the finest at the top. The filtering-tank is fitted, at a few inches above the surface of the quartz bed, with an annular channel communicating by a number of openings with the tank, and into which open the inlet-valve for unfiltered water and the wash-out discharge valve. This annular channel affords a free outlet for the wash-out water, and is a marked improvement on any former arrangement, there being nothing whatever to impede the free discharge of the wash-out water. A third model represented the Archbutt-Deeley water-softening apparatus, all the mechanical operations in connection with which are very simple, and the labour involved light.

Messrs. Geo. Jennings, Ltd., of Lambeth, arranged a number of their well-known sanitary appliances, including some admirable specimens of fitted baths. These are shown in many forms and styles of decoration. A large variety of closets were also shown, including the "Century Syphonic," an ornamental as well as useful adjunct to which is the semi-circular porcelain flushing cistern, which advantageously replaces the old and somewhat unsightly iron tank. A new bath valve, Jenning's patent duplex attracted a good deal of attention, as by its means the water can be supplied to the bath hot, cold or blended, while all fear of scalding the bather or spoiling the enamel through the inadvertent turning on of the hot water first is obviated. The exhibits here comprised urinals, housemaid's sinks, vegetable, salad, poultry, fish, and kitchen sinks, wash-up, bed-pan and slop sinks for hospitals, and other cognate items.

Messrs. Shanks & Co., of 81 New Bond street, were represented at two stands, and showed many of their well-known make of baths

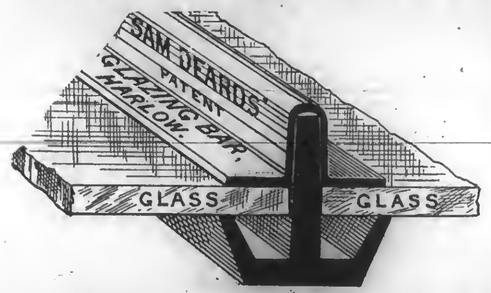
in the several varieties, as plunge, spray, canopied and tubular, in fireclay and porcelain enamelled iron; water-closets and supply cisterns, improved kitchen and scullery sinks, lavatories in vitro-porcelain and fireclay, &c.

"Velure," shown by Messrs. C. Chancellor & Co., Clerkenwell Road, is a new and perfected Japan paint, superseding varnish, with remarkable spreading, elastic and weather-resisting properties. It is sanitary and washable, and it is claimed that it will not crack, chip, peel, blister or fade. It is stocked in 120 colours and any shade can be matched. Samples of "Stripso," another specialty of this firm, were also shown. This is a paint or varnish remover which has satisfactorily withstood the tests of time and experiment, and been proved to be an efficient labour-saver.

At the stand of Messrs. Norton & Gregory, (Westminster Palace Gardens) was shown a new black-line process for the reproduction of architectural and engineering drawings, &c. The results produced by this process can only be characterized as admirable, every line being perfect and the colour not less so. Drawings can be reproduced on paper or linen as may be desired, and the reproductions can be coloured as readily as the drawings. In addition to the beautiful appearance of the prints, this process possesses a great advantage in the rapidity with which the work can be turned out as compared with other "black-line" processes. We may add that Messrs. Norton & Gregory undertake architect's perspectives, which they execute from plans and elevations.

Ripolin, Ltd., 110 Fenchurch Street, E. C., London, showed results of applications of paint to various materials. A conspicuous object at this stand was a panel delicately tinted in flat Ripolin, the effect of which was eminently artistic and pleasing. Ripolin, Ltd., are introducing a new filling, which they strongly recommend for use with Ripolin, whether glossy or flat, for which it prepares a beautifully smooth, hard surface to which the finishing coat can be applied to the great economy of the latter.

Sam Deards "Patent Glazing" for all classes of glass roofing was extensively shown at this Exhibition. We have pleasure in showing our readers an engraving of this glazing bar, for which the advantages claimed are: Its simplicity, cheapness, and durability, and best of all from a colonial point of view the possibility that it can be easily fixed by builders, plumbers, or even unskilled labor. This steel glazing bar with lead cap is made in three sections, C. E. and F., and the steel bars can either be



enamelled, galvanized or lead covered. The same can be supplied all ready for fixing, cut to any desired lengths and easily packed for shipment. Agents are wanted in Canada for this glazing, and full drawings, prices and samples will be forwarded on application to Sam Deards, Limited, 34 Old Broad street, London, E. C., or Victoria Works, Harlow, Essex. There is also a special system for glazing on wond rafters and for fireproof roofs where no wood-work is required; all glazing bars are made "self-locking."

The Rhodes Patent Sash-Hanging Co. had an extremely interesting exhibit of a valuable invention for raising the heaviest sashes instead of the ordinary and usually inefficient smooth-grooved pulleys, worked by sash-cords, chains or wires. This invention enables the largest and heaviest of sashes to be opened and closed by a child. The fittings consist of a cog-wheel or teeth-pulley and steel chains, which are fixed to the sash and frame in the usual way. The chains are chemically treated to prevent rusting, and there are no intricate parts to get out of order.

The Warrington Bond Iron Syndicate, Ltd., of Manchester, exhibited their patent wall-tie. This is a particularly strong and effective tie, and the fact that upwards of five millions of them have been supplied, shows that it is rapidly coming into favour. There are three varieties, one for cavity work, one for solid work, and a special flat tie which may be used either for cavity or solid work.

Messrs. Candy & Co., Ltd., Newton Abbot, showed a large selection of glazed bricks of various descriptions, but of uniformly excellent quality and colour, granite vitrified paving bricks and channels, buff architectural terra-cotta, stoneware sewerage pipes, gullies, interceptors, &c.

NOTES.

Reports from St. John, N. B., state that never since the time of the great fire in that city has the building trade been so brisk; the supply of competent artisans is far below the demand.

The recent building strike in New York tied up $200,000,000 of capital and occasioned a loss in profits alone of $8,000,000 to the contractors and $13,000,000 in wages to the workmen.

On competion of their contract for the building of the King Edward Hotel, Toronto, Messrs. Illsley & Horn, gave an informal dinner to the sub-contractors and foremen on the different departments of the works.

The police magistrate of Toronto recently imposed a sentence of ten days in jail upon two workmen convicted of having assaulted another workman with the purpose of compelling him to give up his employment. In imposing sentence the magistrate remarked: "It's no use putting a fine on these men," their union will pay it, and it will not be a sufficient deterrent."

The fire loss of the United States and Canada for the first quarter of this year was materially below the average of the same period in recent years. The records of the New York Journal of Commerce place the losses for the three months ended March 31, 1903, at $39,164,800, or $9,000,000 less than in the first quarter of 1902, and $6,500,000 below the corresponding period yf 1901. The March fire losses were unusually light, amounting to but $9,907,000.

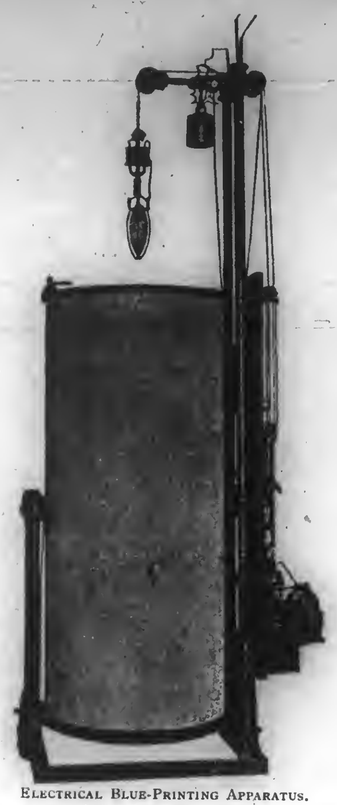
The British Vice-Consul at Lille reports that the violent campaign against the use of white lead for painting has severely affected this industry, of which Lille is the principal French centre; it is very doubtful, he adds, if white lead can be effectively replaced, various substitutes hitherto failing to give satisfaction. Largely increased importations of oxide of zinc, and introduction of a new product called "litophone," suggest that other countries, including the United Kingdom and Germany, quite as interested in sanitary questions as France, profit by the anti-white lead campaign to the detriment of the French producers.

There are three methods of curing chimneys which do not vent well, applied by Count Rumford and all smoke doctors since his time. The first is lengthening the chimney at the top, this increases the quantity of heated air in the chimney, and gives more power or head by increasing the difference between the weight of the air per foot, in and outside of it; the second is contracting the chimney at the throat; this increases the speed with which the heated air passes through it, and gives a heightened initial velocity to the smoke when beginning in its course up the chimney. The third is when there is a deficiency of air in the apartment to feed the flame and blow up the fire, putting ventilators into the sides of the apartments, or into the windows or doors.

A writer in the London Builders' Record gives the following method of removing grease spots on Watman drawing paper:—First remove as much of the grease as is possible by placing the drawing between sheets of clean blotting paper (preferably white) and ironing the spots with a moderately-hot flat iron, constantly changing the position of the blotting paper so as to expose a fresh unsoiled place and continuing this until the ironing no longer causes any discoloration. Then, if it is required to still further discharge the grease, take fresh blotting paper beneath the drawing, and, away from light or fire, pour over the spots benzine, which, as it oasses through the paper, will carry the grease with it. It may be necessary to repeat the latter operation several times before complete success is attained; and be sure and get benzine (syn. benzol) as benzoline is often solp as benzine.

ELECTRIC BLUE-PRINTING APPARATUS.

The importance as well as the general utility of the application of electricity to blue-printing appeals to every architect, engineer and draftsman, to whom the



ELECTRICAL BLUE-PRINTING APPARATUS.

production of blue-prints with the best of solar facilities has doubtless often been vexatious.

The dark and cloudy days of winter, as well as the rainy days in the summer and at all times during the year when the light is poor, smoky or irregular, makes the advantage of having an electrical equipment of great benefit to the possessor. The accompanying illustrations show one of the latest and most advanced types of machines for printing by artificial light.

The apparatus consists of a cylindrical printing frame, composed of two heavy curved plates of glass, bedded in soft material in an adjustable, though rigid, frame, together with two tubular uprights which support the arc lamp and automatic drive mechanism. This drive operates the lamp, having means for lowering it through the cylinder and then automatically raising it again to its former position.

The cylindrical frame revolves on trunnions, so that it can be swung to a horizontal position, which is the most convenient method for inserting or removing tracings and paper from the frame.

In operating, the cylinder is revolved to a horizontal position, and the tracings and sensitized paper are placed around the outside of the cylinder, being confined by stout canvas covers which are drawn tight by turning a lever, thus ensuring perfect contact between tracings, sensitized paper and the glass. The cylinder is then swung to the opposite horizontal position and the same manipulation repeated, after which it is returned and locked in vertical position and is ready for printing.

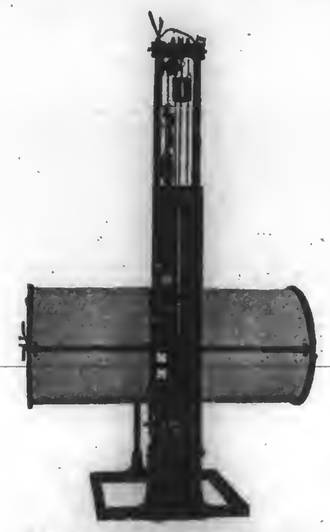
By simply touching a lever the arc lamp starts in its descent through the centre of the cylinder at a speed which can be regulated to suit the sensitiveness of paper employed. When the lamp has reached the lowest point of printing surface, it automatically reverses its motion and quickly returns to its original position above the cylinder.

The characteristic features claimed for the apparatus are as follows :

The machines are self-contained; no bracket or pulleys on wall or ceiling are required.

The automatic drive mechanism for raising and lowering the lamp is a novel, ingenious and reliable device. The downward movement of the lamp is even and steady, and can be regulated at will, to take from five seconds to an hour, depending upon the degree of sensitiveness of paper used.

When the lamp has passed the printing surface, thereby completing the exposure, the motion of the lamp reverses automatically, and returns quickly to its original



ELECTRICAL BLUE-PRINTING APPARATUS.

position. No time is lost and no hand labor is required.

The limit of the motion of the lamp can be set according to the size of the prints to be made.

The arc lamps furnished with the machine are of a special pattern and the best adapted for the purpose, giving the highest actinic effect and a strong, uniform and steady light.

When an advertiser complains that his advertisement does not interest the readers of a paper, he might do better to change his ad-writer than to change his paper. The public is anxious always to be interested, and if the advertisement fails to do it, the fault probably lies with the advertisement and not with the public or the newspaper.—PRINTERS' INK.

OFFICE PRACTICE REGARDING HOURS AND VACATIONS.*

The employees of our office petitioned recently for an extension of the Saturday half-holiday, which we have been giving during the summer season, to continue the whole of the year, and, upon making inquiries from a number of architects as to their custom, and finding it is quite general to give the half-holiday for the whole year, we granted the request of our employees, and anticipate that this additional leisure time will be as much appreciated by the members of the firm as by our assistants. It then occurred to me that it might be of interest to this association to know what is the general custom in regard to office hours, holidays and vacations, and therefore sent inquiries to a number of architects, and have replies from nineteen offices, which are sufficiently representative of the profession to indicate the general custom.

Three offices have a seven-hour day ; six have seven and one-half hours, and eleven have eight hours ; more than one-half, therefore, having eight hours as their working time.

Two offices begin work at 8 o'clock, one office at 8:15, twelve offices at 8:30 and three offices at 9.

One office has set no time for beginning work, the employees being expected to work eight hours, and those who come early leave early, and those who come later stay until their eight hours are completed ; the architect claiming a certain convenience in this for a small office, though, of course, it would be destructive to discipline in a large office.

The hours for closing are divided about equally between five o'clock and half-past five. There is an allowance of one hour for lunch in nearly every case.

In regard to Saturday half-holidays, six offices give such holidays during the summer months, twelve offices during the whole year and one office closes at 3 p.m. on Saturday, as I understand, for the whole year.

In regard to vacations, the custom seems to be universal to allow two weeks' vacation with pay to all employees who have been in the office a year or more, but not to those who have worked for a shorter time. It would seem that there ought to be a general uniformity of practice in all architects' offices in one city in regard to the matter of office hours and holidays and vacations. Apparently in Chicago the two weeks' vacation to permanent employees is generally recognized, and the Saturday half-holiday, which has been coming to be recognized more and more in the community, will doubtless be extended to take in the whole year by all architects, when they learn that the majority of offices are already granting that privilege.

In the matter of office hours, the preponderance is decidedly on the side of the eight-hour day, although there are enough offices that work for a shorter time to present a decided lack of uniformity. This is a matter which might be well discussed by this association, and perhaps a uniform custom could be brought about.

There are other matters of business management of our offices which could be taken up with advantage, as, for example, the question of overtime—as to the policy of working evenings, and whether there should be extra pay for such overtime. My own opinion on this point is that overtime should be avoided whenever possible, and that in most instances this can be done by the exercise of foresight. To work evenings for any length of time will certainly exhaust the energies and render the daywork less efficient, so that the gain is comparatively small and not in proportion to the additional effort, and that better results can be secured by urging every one to extra exertion during the regular office hours, at the time when there is a rush of business, and supplementing by additional help ; and that in the case of permanent employees there should not be extra pay for overtime. If every one knows that in case the work is allowed to drag along and is not done on time they must stay and work at night, it will be a stimulus to each one to finish his work during the day and thus avoid the need of overtime ; and when such an effort is insufficient, then the working force should be increased during the day, rather than to overwork by the addition of hours.

This brings up a point—that we often find it difficult to get extra help when we need it and would be glad to pay for it, and thus are forced to overwork ourselves and our employees. There should be some bureau of intelligence to supply draughtsmen on short notice. I have recently learned of such a bureau, namely, the Engineering Agency, in the Monadnock block, but this agency limits its work to supplying men for permanent positions. Now, probably the most frequent use that an architect would have of such an agency is to get one or two men to do tracing for perhaps not more than a week, and the fees charged by this agency are higher than one could afford to pay for positions lasting only a week. It seems to me that it would very properly be one of the operations of this association to have a bureau of information for architects' offices, and if our secretary is willing to undertake such work, I am certain a fee could be established that would reimburse him for the necessary expenditure of time. The object of this association is to help its members in every way possible, and it would certainly be a great assistance to our profession to where we can send on short notice and get extra help. At the same time such a bureau of information would be of great benefit to draughtsmen. One of the advantages of locating an architect's office in a large city is the facility with which skilled assistants can be found, and we could still further increase that advantage by such a bureau of information. If this work should be taken up by the association, its benefits would properly be limited to members of the association and thereby increase the value of membership.

*Paper read and discussed before the Chicago Architects' Business Association and the Illinois Chapter, A. I. C., April 14, 1903, by Normand S. Patton, architect.

THE SIMCOE STATUE.

The statue of John Graves Simcoe, first Governor of Upper Canada, a reproduction of which appears on our illustration page, unveiled May 27th, 1903, is the work of Walter S. Allward, a young sculptor of Toronto, and was won in competition from English, Scotch, and Canadian artists.

The Bronze is 9-6" in height ; the pedestal is of Stanstead granite, 10'-3" in height and was designed by the sculptor and cut by the McIntosh Granite Company.

The bronze casting was made by the Henry Bonnard Bronze Company, of New York.

TELE-PHOTOGRAPHY FOR ARCHITECTS.

We are indebted to the London Builder for information regarding the advantages for architectural photography, of using the tele-photo lens. By its use it is possible to take a piece of detail on a large scale at a height impossible with the ordinary lens. The following suggestions of the author may be useful to those who may care to experiment with tele-photography. He says: "All photographs of detail should be taken in diffused light if possible. If the sun is shining, sometimes an obliging cloud will obscure it for a time sufficiently long to enable an exposure to be made in diffused light. If a series of photographs is to be made of a large building or cathedral, begin work in the morning on the south side and go to the west as soon as the sun interferes; the north side may be safely left to the afternoon, when any exposures should also be made upon the east end. The final focussing of the tele-photograph should be made with the same stop in the front lens as that which is used for making the exposure. Do not take tele-photographs of detail against the sky if it can be avoided. Somewhat different conditions come into force when more distant views of buildings are the objects to be portrayed. In many cases sunlight will be helpful, especially if the sun is not too high and overpowering."

PRESERVATION OF IRON IN CONCRETE.

In the spring of 1901 the German Department of Public Works undertook a thorough investigation of the condition of the concrete slabs and the iron imbedded in them in a revetment wall built in 1890 in Berlin. The wall consisted of reinforced concrete slabs between beam posts, resting on piles cut off below water and held horizontally by back-stays, which is reported in a recent issue of the Zentralblatt der Bauverwaltung. The reinforcing consists of horizontal 3/8in. round iron rods in number depending upon the earth pressure acting on the slabs, and of vertical rods about 3-16in. in diameter. The vertical and horizontal rods are tied together by wire so as to form a netting.

To investigate the condition of the slabs and the iron imbedded in them, nine slabs were chosen which showed cracks and other injuries, and twelve slabs which had a perfectly good appearance. Thirty-two holes about 10in. by 10in. were chiselled out, completely uncovering the rods, and at all places also, where marked injuries were noticed, the concrete was removed completely from the rods. The horizontal rods were 0·04in. to 0·4in., and the vertical rods 0·4in. to 1in. from the faces of the slabs. In an injured slab three horizontal and two vertical rods were uncovered. The greater part of the upper horizontal rod was covered by a thin layer of rust, and the mortar, from the rod to the face, was destroyed. The two lower rods were free of rust. The vertical rods were somewhat rusty at several spots. In another injured slab, the uncovered rods, four horizontal and four vertical, were all equally rusty.

In a slab, which appeared on the outside to be in perfectly good condition, three horizontal and four vertical rods were uncovered. The two upper rods were rusted the same as in the slab first mentioned, but the lower rod was free of rust. The four vertical rods showed slight rusting at several spots. In another uninjured slab, all the rods uncovered, four horizontal and three vertical were found to be free from rust.

In a slab in the upper row, the concrete had scaled off for about 4in. above the bed joint, and short distances each side of the post. The uncovered rods were much coated with rust on the face. In another slab the concrete had cracked off near the lower edge for about 4in. A horizontal rod laid 0·2in. from the face had become loose, and was much rusted on the face. In still another slab, seven horizontal rods became loose because the concrete layer covering them had cracked off. The rods were much rusted. Three other slabs showed the same injuries. The concrete layer, which was only 0·12in. thick, had cracked off, and the rods which were laid bare began to rust.

Some conclusions as to the building of reinforced concrete slabs of this type and the arrangement of the imbedded rods may be based on these observations. Rods with incipient rust were found in a relatively great number in injured slabs and in slabs in good condition externally, but destruction of the concrete was found almost invariably only where the rods were near the external face. At such spots, having only a thin protecting layer of cement, it was found that the rod was much rusted on its front only while the rest of the surface remained clean. Apparently the injury to the slabs may have been caused partly by the improper location of the rods, even, when free from rust, and partly by the use of rusted rods. Wherever rods free of rust protected by a good layer of cement of 0·3in. to 0·4in. and more in thickness were uncovered, the slabs showed no injury. It was also observed that the mortar adhered less strongly to the rusty rods than to the rods free of rust. From the latter the mortar had always to be removed by the point of a hammer.

Since the greatest bending stresses take place at the middle of the slab, it will be well to bend the rods so that they will be near the centre of thickness at the supports and the requisite distance from the face in the middle. No greater difficulties will be encountered in tamping the concrete than are encountered with straight rods which have to be bent in at the ends because of the flanges of the I-beam post. No accuracy is required for the curve of the bent rod.

At the session of the Ontario Legislature which has recently closed, a bill was passed extending the powers of the Toronto Art Museum to enable it to accept large donations and bequests, borrow money and expropriate land. Mr. Byron E. Walker in urging before the Committee of the Legislature the passing of the bill, pointed out that the Association had already bequests and donations sufficient to enable it to proceed with the erection of an art gallery and museum as soon as the enlarged powers were secured. We may therefore expect to see this important project assume tangible form in the immediate future.

The traveller through the streets of our cities these early summer days, writes Mr. Barr Ferree, in the Architects and Builders' Magazine, will note a prodigious amount of building going on, but perhaps not much architecture. Although building should be architecture, unfortunately it frequently is something else. It is a pity that this should be so, for once a building is erected it is likely to stand some time, and if it is not truly interesting it had better not be built at all. The architect who writhes at unfriendly criticism should bear in mind that what is written may be lost and destroyed; his building, be it ever so atrocious, must stand, and stand before the public which is helpless to remedy it. The bitterest thing a critic ever said is mild and harmless compared with the ceaseless and unavoidable permanency of a building.

ON ARCHITECTURAL NOMENCLATURE.

Lovers of architecture should be glad that their love is not one of the "ologies," and is practically free from those Greek and Latin compounds which it seems to be the delight of scientists to introduce into the English language, says a writer in Building News. Though architecture is essentially a Greek word (as it is fitting it should be), it does not suggest the "specialist" which clings to the "ologies," and if we examine the architectural vocabulary, it is surprising how simple and elementary very many of the terms are. It is very pleasing, too, when we examine the relation between each feature and its architectural name to find that we can trace its origin, nature, and purpose through that name.

If such a vocabulary is made out, a very great number of the most common terms used in building will be found to be borrowed from natural forms, especially those of animals, and the physical system of the animal kingdom finds its counter-part in architecture.

Thus the very terms of the art show the noble principles on which the true forms of it is developed—they show both the laws by which a building stands, and the canons by which it is decorated. If the terms are belied or violated, their meanings, which remain, at once point out the barbarisms, and show up the falsehoods. Just as when we call a spade a spade, and someone chooses to call it a pitchfork, nobody is deceived who has any idea of what a spade really is.

Firstly, as to the laws of building in a universal sense. Starting with the solid foundation, the footings spread out to receive the walls, with their face and back. The wall is capped by the coping (Dutch cop = head), and where columns exist they have their capital (Latin caput = head). Further, the walls undergo the process of toothing. The vaults are completed with ribs, haunches, and crown; the roof has its hips, the rafters their heels. The window sills are throated. The very building, finally, has its wings. (It is interesting to note that the epithet of "wingless" applied to the little temple on the Athenian Acropolis is now understood by some to refer to the building itself and not to "Victory"— a theory which gains in probability on remembering the Erectheion in close proximity, which has so many wings).

Leaving the general structure of the skeleton of the building, we find among moulding such charateristic terms as swan's neck, bird's beak, dog-tooth, and also the wave moulding.

The last is especially pleasing as it is almost the solitary expression in architecture of the ocean. While it is true that flowers or foliage afford the quintessence of architectural ornamentation*, the sea contains such varied and grand forms and waves, that a "style" developed from wavecrests and ripples would be almost as fascinating and as equally magnificent as the most elaborate system of tracery or carving, with "foil", leaf, or "lobe" as a basis. The "wave-tracery" (suggested, no doubt, in the Flamboyant curves, but there literally developed from flames) is really a phase of Gothic yet to be developed and admired. Something far different, please, from Greek Fret or guilloche spirals, of which Ruskin wrote scornfully by pointing out that "into which the great Greek architect transforms the sea." But conceive how a wave would cast itself around a huge bell capital, and fall in dripping foam down the shaft! It is surprising that in such a water-city as Venice, with all the wealth and dexterity of Byzantine marble work on capitals and mouldings, no expression of their waterways and lagoons is conceived. The Japanese might do it, as surely they have yet to develop a style of architecture in which the peculiar qualities of Japanese art can exert their influence. The spirit of waves, as above suggested, is found very strongly expressed in the colour-print of Hiroshige and other artists. Perhaps few people have such a vivid way of catching the extract conventional forms of striking natural features. The same remarks might be applied to cloud forms.

Curiously enough, the parts of a ship do find their way into our architectural vocabulary. The keel moulding is characteristic, and there is cabling. On some American plans we lately noticed the delightful use of the word deck for a kind of verandah, and possibly cabin and saloon were originally taken from the ship. As there is no nobler art than shipbuilding, it is appropriate that its influence should be felt in architecture. The anchor is used in decoration, and Venetian masts will soon be adding to the gaiety of our street architecture.

In Greek architecture, if we may examine the original terms, we find the same association with life. The frieze was "life-bearing," and can anyone conceive a frieze more justified in bearing such a title than that of the Parthenon? Look, too, at the Caryatides, or "the women of Caryæ," supporting their eternal burdens of portico or roof. In the cornice we get the corona or crown. It is not quite clear why the pediment (i. e., foot) should be so called unless the idea was mixed up with that of the pyramidal form of a tripod acting as a foot. Then, again, there is the Greek moulding astragal, from one of the vertebræ of the neck.

Leaving architecture strictly, in carpentry and joinery the same nature of words holds good—witness dovetail (the French "swallowtail"), foxtail, herringbone, and tusk tenon.

We have by no means exhausted the list, and may mention bird's-mouth, bull-nose, feather-edged, tongue, dog-legged stairs. And, in conclusion, we may remind the weary reader of those delightful "heavenly twins" who put forth "flying buttresses" as signs of bad weather.

*In flower tracery we get the rose window. Ruskin has suggested a series of tracery devoted to every variety of flower, just as the Japanese, in their exquisite, natural flower decoration, devote one room to one flower.

AMERICAN LEAGUE FOR CIVIC IMPROVEMENTS.

The annual convention of the American League for Civic Improvement was held at Chautauqua, N. Y., July 13th to 18th, and the Ontario Association of Architects was represented by Mr. Wm. R. Gregg. There were conferences upon Rural, Village, City and National Improvement, at which representatives from many localities spoke, reporting a most encouraging year's work. Lectures were given by Mr. Clinton Rogers Woodruff upon "Municipal Progress," Mr. W. R. Eastman upon "Library buildings," Mr. Albert Kelsey upon "The Model City" and Mr. J. Horace McFarland upon "The Harrisburg Plan." Also two series of lectures were delivered, one by Prof. Chas. Zueblin on Contemporary Society and the other by Mr. John Quincy Adams on Art.

Mr. J. Horace McFarland was re-elected President and Mr. E. G. Routzchen is Secretary. An annual dinner and an afternoon's excursion on the lake contributed to the enjoyment of the delegates. The next annual meeting will be at St. Louis.

The Canadian League for Civic Improvement which was formed lately in Toronto is a similar organization.

CORRECTION.

We regret that a mistake occurred in the advertisement of the Henry Richards Tile Company appearing in the British Supplement in our May and June issues. The name connected with the Company's Sanitary Works should have been printed Edward Johns & Company, not Edward Innes & Company.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO., of Toronto, Limited, Publishers,

Confederation Life Building, TORONTO, CANADA.

Telephone Main, 2362.

Branch Offices:

IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 19th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

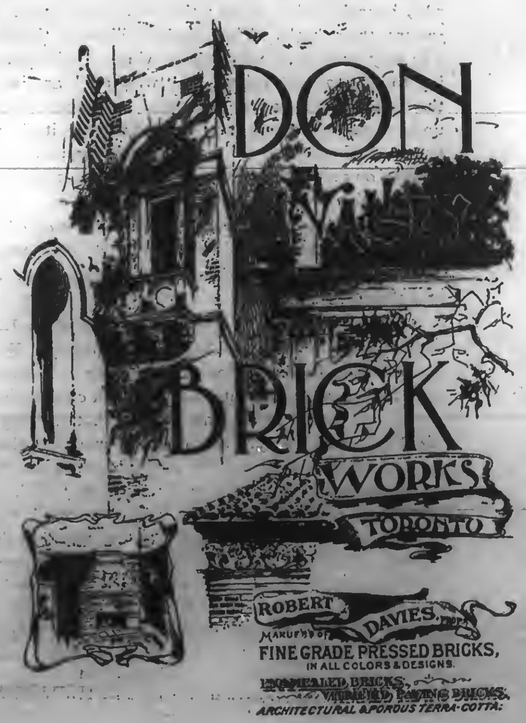
NOTES.

In the building of the City Hall of Philadelphia, a portion of the brickwork of the tower was laid up with cement mortar and another portion was laid in lime mortar. The work was faced with marble. As a result, wherever the marble facing was backed with brick in lime mortar, the marble facing crushed and spalled and had to be cut away and refaced. Wherever cement mortar had been used no harm came to the marble facing.



THE BUILDING STRIKE IN TORONTO.

The strike of the carpenters and builders' laborers inaugurated in Toronto more than two months ago has failed. The contractors offered the carpenters 32½ cents per hour, or within 2½ cents of their demand, an increase of 10 cents per hour above the wages they were receiving two years ago. This offer was refused and the resulting deadlock has continued ever since. The builders' laborers demanded 30 cents per hour and went out on strike rather than accept the contractors' offer of 27 cents. On several occasions recently the strikers sought conferences with the Builders' Exchange but were told that the employers had made their best and final proposition. In his last letter written but a few days ago, the Secretary of the Exchange intimated that that body had withdrawn its Committee and positively declined further negotiations. This brought matters to a climax, and the strike of the carpenters and laborers was declared off. The early termination of the painters' strike may now be looked for. On excellent authority it is learned that five hundred men are now at work in this trade, and that of this number about 460 are receiving 30 cents or less per hour. Under these circumstances there is not the ghost of a chance for the strikers to succeed in their demand for 35 cents per hour.

NOTES.

The master plumbers of Sydney, Nova Scotia, have recently formed an association.

Mr. W. J. Burroughes, formerly a well-known Toronto plumber, now of London, Eng., is at present on a visit to Canada.

Robert Snarr, a prominent contractor, of Toronto, died at his home in that city last month, aged 51 years. Among the important structures erected by him were the Home Life Building, McMaster University and the Mercer Reformatory.

The Trade Papers Publishing Co., High Holborn, London, Eng., has published Part I of a work by J. Petrie devoted to an explanation of the methods to be adopted for graining and marbling. The work which is to be published in fourteen parts, is illustrated by colored plates with explanatory notes.

SURVEYORS ASSISTANT

Age 20. Open to engagement. Quantities, details, and surveys. 5 years London and provincial experience. Advanced certificate construction. Will send photo, specimens, testimonials, and further particulars. NORMAN PHILLIPS, 1 Heigham Road, Norwich, England.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingles stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

Stained woods and descriptive literature sent free upon request.

TERRA COTTA FIREPROOF BUILDING MATERIAL

POROUS TERRA COTTA among underwriters is classed as preferred risk, and the schedule of rates now enforced in the city of New York shows a difference, often great, which, computed means an annuity on large sums of money.

This indisputable fact appeals to architects as representing clients who may soon be exposed to the same classification in Canada. An apparent saving in selecting cheaper fireproof material may be more than lost through increased insurance cost.

POROUS TERRA COTTA FIREPROOFING is a credit to the buildings in which it is used and increases their selling value.

The **Montreal Terra Cotta Lumber Company,** Limited,
N. T. Gagnon, Selling Agent, 204 St. James St., Montreal, Canada.

A DISCOVERY IN BRICK MAKING.

Mr. D. J. Acheson, of Niagara Falls, N. Y., claims to have discovered why the Egyptians used straw in the manufacture of their bricks. According to Mr. Acheson, it was not alone as a binding material, but because the tannin extracted by the soaking of the straw in water added greatly to the strength of the bricks. By treating clay with an extract of straw Mr. Acheson has shown a 50% increase in tensile strength and an increase of plasticity, with a decrease of shrinkage.

The clay is worked with water in which straw has been boiled. So little as one-half of 1 per cent. of tannin is said to develop a wonderful effect, the clay requiring 13 per cent. less water to make it soft. The maximum effect of the process and treatment, however, seems to be obtained by the use of 2 per cent. of tannin in a ten-day treatment. The treatment is merely keeping the clay wet with water in which tannin is dissolved, which can be done in vats.

Besides the above-mentioned 50 per cent. increase of strength in the burnt form, the clay in the sun-dried form acquires an increase of 350 per cent. in tensile strength.

As a result of this discovery Mr. Acheson has patented a combination of clay and tannin under the name of "Egyptianized clay.

AN OPPORTUNITY TO BE IMPROVED.

The meeting in Montreal next month of repesentatives of the leading Chambers of Commerce of Great Britain should prove an event of great importance to Canada. No effort should be spared to afford these representative business men of Great Britain opportunity to see every part of this Great Dominion, and judge for themselves of its resources and trade possibilities. The subject of prelerential trade within the empire, now the leading topic in political and commercial circles throughout Great Britain, will doubtless constitute one of the leading subjects of discussion at the Montreal Conference.

Fire Protection Engineering.

The Armour Institute of Technology, Chicago, has recently established a four years course in Fire Protection Engineering. Special instruction will be given three hours a week during the second year in the chemistry of fire protection, eight hours during the third and fourth years in fire protection engineering, and eight hours during the fall and winter terms of the fourth year in schedule rating, special hazards, underwriters' requirements and insurance practice.

Colour in Churches.

It is usual for writers about mediaeval architecture to speak with great sadness of the glories of the wall colouring, that time, assisted by whitewash, has caused to disappear. It is true that the small portions of frescoes that remain here and there have usually the peculiar softness of colour of a faded fresco. But it is not likely that the colouring was always so. And if it were—with the varieties of coluor and scale, the beauty, if there was any, must have been the beauty of a patch-work quilt; interesting perhaps in part, but queer as a whole. But as a matter of fact, what remain in the way of wall paintings are hideous in their grotesqueness, regarded singly, and could give no real pleasure, or be of real value, except to an antiquary. The church, when it is scraped down to the stone, is really more suitable and more pleasing. The present generation owes a debt of gratitude to the vandalism of the past. The best architectural colour is the colour of stone, especially of old stone. This is equally true of wood. Looking up at a perpendicular roof of carved oak beams, whitened on the outer surfaces of the mouldings and darkened in the hollows, one thinks with horror of the fragments of red and blue and gold which are said to be visible to close inspection. What if the whole roof were to be covered with them! The writers upon the church may regret, as much as they like, the loss of this ancient blaze of colour, but an architect is thankful.

Common Entrances.

A good arrangement, constantly to be met with in London, is a row of houses set back some distance from the road and having a common carriage drive. It is in fact a double road, as far as it goes; or, when both sides of the street have the same plan, a triple road; the public highway flanked by private entrances, which turn out into the public way at each end of the block and are divided from it by a railing of

some kind and a row of trees. In one case at any rate, this plan is carried through the whole length of the street and makes a handsome street of it.

This is nothing more than the ordinary spacing of town lots, so common in Canada; where each lot, whether the houses are detached or in rows, is too narrow to admit of a carriage entrance from the street up to the front door; and where the building line is set back so far from the street that, without a carriage entrance, any one arriving or departing in a carriage must cross some fifty feet of pathway, exposed to possibilities of rain or snow. In the case of the London house, the kitchen department is in the basement and the garden is on the interior side of the house, so that the only use of the set back on the exterior side is as a set back—to remove the house from the public way. That the space should be occupied by a private driveway is no loss but a gain. In our cities, as the rear is usually occupied by the service department and a yard, the set back in front becomes the garden and an airing place for the family; but there are occasional variations in which the London plan would be the thing to aim at.

In order to have the best effect of privacy and to keep the street well marked, a wall is necessary, or at least a railing. A plain, low wall is better than anything that can be made of wood, and even better than iron for purposes requiring clear distinction; but the most beautiful form of street wall—which is something that should define without concealing, and that, while serving its purpose, should also serve for adornment—is a low wall with a railing on top.

Winter Foliage.

There is great beauty in the mere trunk and branches of a well-shaped tree; and to have this before the eye in winter, especially when, seen through a window, the ramifications form, as it were, decorative pattern, running through the panes of glass and crossed by the sash bars, would be sufficient reason for having trees in a garden if there were no such thing as foliage. But when the time comes for the foliage to break out, it always seems to be a little better than we expected, and we look forward with regret to the time when it will fall again. As a matter of fact, the thing which particularly surprises us always is the abundance of the foliage. It is only by noting in one spring the extent to which the full sized leafage surpassed our expectations that we can be prepared for what to expect when summer comes again. This should be the cure for the discontent of winter; for the green gloom which we enjoy in summer would be an uncomfortable surrounding to a house in winter. But a green object that casts no gloom is as good in winter as in summer. What is wanted is an evergreen tree of some sort that does not grow too large and is not too funereal.

Japanese trees of this sort seem to answer every requirement except proof that they will stand our climate. They grow well in the north of England where it is very cold at times; yet it is not so much cold according to the thermometer as just beastly cold; and it is only thermometer cold that vegetation seems to mind, on the other hand, however, there is no protecting snow; but the sort of open winter that a few years ago decimated our hedges and climbers. Japanese ivy failed in that year when it was planted against a south wall; no doubt because its roots, when not protected by the cool covering of the snow, were beguiled by the sun to send up sap, only to have it frozen when the sun had passed. Ordinarily, Japanese ivy succeeds and the presumption is in favor of Japanese fir.

The peculiarity is, like other Japanese plants, a variegated foliage which relieves the gloom that is so unpleasant in other evergreens. A variety called Retinospora Aurea makes an excellent garden tree, in summer or winter. It does not grow too tall, has a fine close foliage, which makes good masses, but of a delicate texture. The tips of the leaves are nearly yellow for an inch or so, which brightens up the tree and gives its light and shade the *chic* effect of a piece of colored modelling which has had the tint wiped off the highest surfaces.

There is another Retinospora in which the foliage on the back part of a bough is of a very dark green, while the tips are of a very light, almost silvery, tea green. The effect of this is even more delicately beautiful than in the golden variety.

Table of Architectural Periods.

The following is a convenient table of architectural periods drawn up by an English architect:

A.D.				
1200	Early English.	Early English.		
1250		Gradual Change		
1300	Decorated	Gradual Change	..... Edward I	1272
			..... Edward II	1307
			..... Edward III	1327
1350		Gradual Change	..... Richard II	1377
			..... Henry IV	1399
			..... Henry V	1413
1400	Perpendicular		..... Henry VI	1422
			..... Edward IV	1461
			..... Edward V	1483
1450			..... Richard III	1483
			..... Henry VII	1485
1500		Gradual Change	..... Henry VIII	1509
			..... Edward VI	1547
1550	Elizabethan		..... Mary	1553
			..... Elizabeth	1558
1600			..... James I	1603
	Jacobean		..... Charles I	1625
1650			..... Commonwealth	1649
			..... Charles II	1660
1700				

The steel work in Chicago's new postoffice has been given three or four coats of graphite, one at foundry, one at building and two coats after erection.

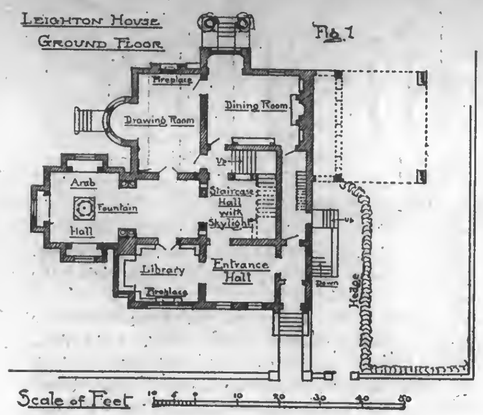
It is reported that the deposits of silica and gypsum near Truro, N. S., will be developed by a New York company. The ores will be shipped to the United States by water from either Bedford or Richmond, and from 100,000 to 150,000 tons a year will be mined and disposed of. Messrs. King, of New York, are said to be developing their plaster property at Hillsboro', Albert County, New Brunswick, which they have owned for a number of years. If the quarry turns out right it is expected that a large business will be done and their plaster mill in New York will be supplied directly from the quarry.

NOTES OF TRAVEL.—III.

Leighton House

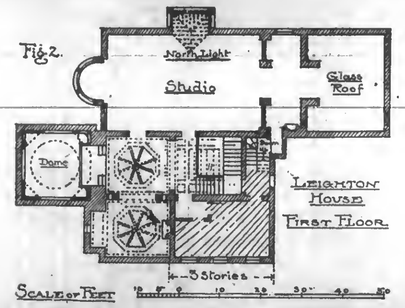
(Concluded)

The entire suite of halls is paved with mosaic work of marble. The openings, between the different parts, are finished with marble columns. This solidity is carried to the staircase, in which the steps of the first flight are of stone. This flight is contained by a stylobate wall, on which stand marble columns to take the staircase wall above; for the first flight of the stair is



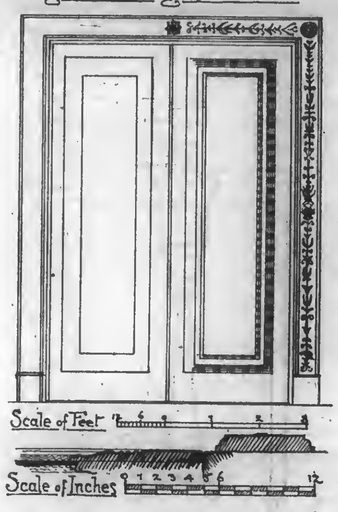
not within the staircase proper, but in a space beyond, which forms a sort of vestibule to the drawing room and dining room. The camparative retirement of the drawing room and dining room doors and of the bottom of the staircase, and the retirement of the latter behind a wall and a screen of columns, are good points in the plan; and an appearance of spaciousness and dignity is given to the hall by the added size and richness.

The drawing room depends for its interest upon the



bow in the centre of the west side. These windows open down to the ground, and from the window in the middle proceeds a flight of stone steps, leading to the garden. The boundary of the garden is not more than fifty feet in this direction. The direction of its greatest extent is to the north, where the limit is practically out of sight. The garden is large and has trees which intercept the sight of what is beyond it. The window on this side does not seem to have been specially designed for looking upon the garden—not downwards at any rate. The window is four feet wide and the stool is not less than 3'. 6" high. The fireplace is under it; and no doubt, in winter, the branches of the trees, as seen through the window, would form a good decoration over the mantel; better if the sashes were barred, which they are not. But, unless there was some idea of gaining wall space for large paintings on the east, with which a fireplace would interfere, the result does not seem to justify the arrangement. The fireplace opening is a semicircle, about 2' 6" in diameter, faced with white marble, inlaid with black in the form of an iris or rush-leaved plant, to decorate (rather thinly) the sides and spandrils. The mantel shelf runs into the window recess.

Fig. 4 Drawing Room Door.



The wall of the drawing room are painted a deep red; the ceiling is white, panelled with moulded plaster beams; the wood work is finished with shining, though not glossy, black paint. This is the manner of finishing the woodwork throughout the house. It is rather sombre, but dignified; and in respect of its shininess has this point in its favour, that the diffused light within doors is better calculated to give effect to mouldings designed to catch light than to those intended to make shadow. The incised work of the door architraves, in the drawing room, is peculiarly indebted to the way in which the wood is finished. A first sight of this incised ornament did not command admiration. Sunk patterns are but one remove from jig-saw work, and one might expect something better in Lord Leighton's "front room." But for some reason this ornament gave pleasure, and close inspection showed that the sinkings are not square, but pitched or curved. Stems are v'ed, but flowers and leaves are delicately and not monotonously curved and the shining surfaces reflect light like an intaglio. The flowers or rosettes, at the bottom, centres, and angles of the architrave are gilded. The panel moulding has a curious, delicate effect of being scored horizontally. Inspection showed that the mouldings are, at this member, subdivided by a number of small beads, which are run with a surfacethat waves on the plane of the face of the mouldings, producing horizontal bands of light and shade.

The Dining Room is trimmed in the same manner

as the Drawing Room but not with the same detail. The gilding is here carried into the baseboard of which the top member is gilded. A gilded moulding also finishes the bottom of the wall beam of the ceiling. It is not a picture moulding, but is evidently introduced for the line of gold: the pictures are carried on brass rods below. The ceiling beams, which are deep and heavily moulded, are coloured a deep red, something near crimson in colour. The walls are deep red also—a paper with a small pattern, a little lighter than the ground. The panels of the ceiling are white.

Lord Leighton evidently valued light from above. All the ceilings in the rooms, are white; and the distinguishing characteristic of the upper floor is the skylight in every ceiling. The staircase has a long panel in plaster, next to the wall all around, and the remainder is covered with a barrel shaped skylight. The staircase hall, with its columns, has, in consequence, all the effect of an open court; and the striking

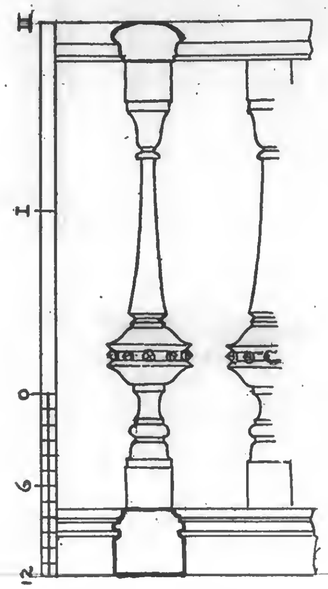


Fig. 6. Baluster.

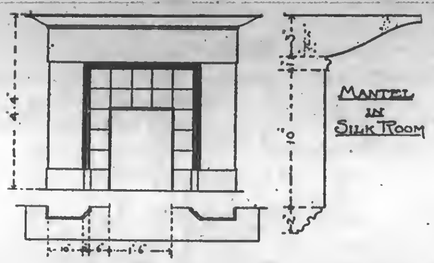
balusters (which like the rest of the woodwork are a shiny black) are shown to advantage.

The remaining room down stairs—the Library—has black bookshelves, to the height of the window stools, round most of the walls. There is a fireplace in green marble, under the window again about as effectually tucked away out of sight as it is possible for a fireplace to be. Lord Leighton does not seem to have been of the same mind as the rest of the world who have adopted the Latin word for a fireplace, Focus, as the general term for an essential central point.

The most instructive feature in this little room of which the ceiling is as high as the other rooms on the floor, is its cornice, which must be of 3′ 0″ girth and has a good effect upon the proportions of the room. It must be remembered that there is a heavy base of book shelves.

Upstairs, the distinguishing characteristic is abundance of light. The double hall, between the staircase and the upper part of the Arab Hall, was evidently intended for the display of pictures. Each division has a skylight, in the form of an octagonal pointed dome, in the middle of the ceiling. The walls are hung with stuff of one colour: canvas of a bronze yellow in the northern division, and gold yellow silk in the southern. This latter division is dignified also with a marble

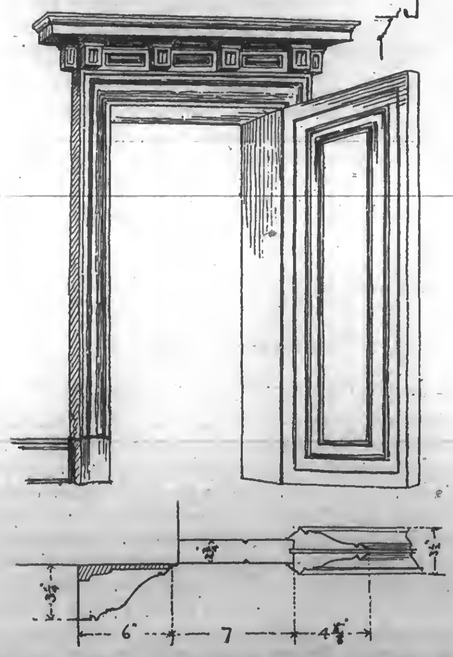


mantel, which, though simple, is worth a drawing. Marble columns supporting a plaster beam divide the spaces.

A couple of steps up from the floor is the level of the projecting lattice window which overlooks the Arab Hall. Latticed casements open so that one can look down into the hall; and the sound of the water, falling back into the basin, ascends from below. A large plant standing upon the platform between the steps, shows well under the skylight, with the lattice work as a background.

The Studio is of course the principal room of the

Fig. 5 Studio Door.



house in scale. Its finish is correspondingly bold. The main door in the centre of the Studio, which is shown

above, is made a central feature by the vigour of its detail. The secondary door, to the middle hall, is subordinated by its flatness. The shaded section shown at the back of the section of the architrave, in the drawing, represents the whole projection of the artritrave in this door; and its panel is similarly subdued.

The north light of the studio runs practically from floor to ceiling; and, being in the form of a projection, has a hipped roof, which is also in glass, giving a vertical light. The original studio ended with the gallery, which is now a passage room between the large studio and a later addition with a glass roof. This addition is carried on iron columns. The passage room is also clear of the ground, but not to the same height; there is a sort of well, (for the storage of canvases, etc., no doubt,) which extends a few feet below the studio floor; below this the structure is carried on piers. It seems a pity that this space was not included in the lower floor, where it would have made an excellent pantry, adjacent to the dining room, opening off the back hall. There is height enough for both a pantry and the storage well above.

Over the passage in the studio is a gallery, approached by a small stair—which should have been shown in the plan, at the north end, by the little window. A door at the other end of the passage, communicating with the back stair, was evidently the entrance for models. It will be observed that, in connection with this, there is a side entrance to the back hall, at the ground floor; apart from the kitchen entrance, which is by area steps to the basement.

W. A. Langton.

SOME LESSONS OF THE RECENT STRIKES.

As predicted last month the painters' strike in Toronto, like those of the other trades, has collapsed. The present season has witnessed the greatest conflict in the building trades that has ever been fought on this continent. The responsibility for the fight to a very large extent lies with the unions, whose demands were such that they could not be acceded to, and the employers were forced to organize for defence.

In Canada, public sympathy has largely been on the side of the contractor, the general feeling being that the workmen were pressing their demands too far. It is a pity that the men did not realize this fact before resorting to extreme measures and blocking commercial enterprises for the greater part of the year. They appear to have forgotten the old song which declares that "The mill will never grind with the water that is past." Neither will these strikers ever be able to give to the support and comfort of their families the money which they might have earned during the first three months of this season.

However, there is usually more or less silver lining to every dark cloud, and there is reason to hope that some benefits may accrue from the present disturbed conditions. The labor agitators have been discounted not only by the public but also in the eyes of the unions whose interests they are supposed to represent. In some instances they have been proven disloyal, even to the extent of asking for and accepting bribes to call off strikes which were instituted by their advice and direction. This should open the eyes of the unions to the character of some of the men who aspire to be their leaders and will no doubt lead to such a revision of regulations as will curtail the powers of the walking delegate. The unions have been taught that it is unwise to press demands which are out of relation to and not warranted by prevailing commercial conditions. To do so is to alienate public sympathy and court defeat. It may safely be asserted that an earlier appreciation of this fact would have saved the labor organizations connected with the building trades in Canada the very serious set-back which they have sustained.

The president of the International Typographical Union, in an address delivered at the annual convention of that body in Washington recently, advocated effort on the part of labor organizations in the direction of the better education of workmen and apprentices. He upheld the right of the employers as well as the workmen to organize, and suggested, correctly, no doubt, that such organizations might prove to be the mediums through which negotiations between employers and employees could more easily be conducted, and by means of which more satisfactory relations might be established.

If the labor organizations would approach the problem on the broader lines suggested in this address, they would find the employers ready to listen to their representations and to co-operate with them in securing necessary reforms. The interests of both classes are identical and should be so considered.

While the evil results of a long-sustained conflict are still so clearly visible this would seem to be an opportune time to look the situation squarely in the face and see if the policy of the past under which such strife and hardship have been suffered should not be superseded by one which would seek to improve the mental and mechanical ability of the artizan.

The effort to place all workmen on the same level, disregarding the widely varying standards of ability with which the Creator has endowed them, is one of the greatest errors of the union system as it exists to-day, and its abolition should form part of any system of reform which may be inaugurated. Workmen should be graded according to their ability and the rate of wages arranged to correspond.

Attention should be directed to devising means for improving the standard of workmanship, so that the presentation of a union card might be regarded as a guarantee of the competency of the workman. This important matter has hitherto received no attention whatever, but, on the contrary, employers have been made weary and disgusted by the repeated demands for shorter hours and more pay.

What is now wanted is a policy which will encourage workmen to make the most of the ability which God has given them, and teach them that by so doing they will achieve the highest measure of success in life, financially and otherwise. Such a policy would receive the approval and support of employers, would fit workmen to become themselves employers, and go far towards re-establishing the sympathetic relations which formerly existed between employers and their workmen, but which unfortunately have of late been in a measure destroyed.

A Chicago court recently decided that the owners of a building having a smoky chimney are liable for damages to persons whose property is injured by the smoke and soot. The award for damages was $1,500.

FINISHINGS IN WOODWORK.

By Fred T. Hodgson.

More attention is now being given throughout the country to the artistic finishing of houses and fine business structures, and more expert carving is done for the purposes named, the appearances indicate, than in the manufacture of furniture, which industry for a long time laid claim upon the greater share of this class of mechanical talent. The reasons for this may not be fully self-evident or patent, but it would seem that it is largely because the real value of hardwood in this direction had never been fully realized or understood in this country, and because, also, the real high art in decorative architecture is scarcely native to American ingenuity and talent, which is famous in other ways, since there are oriental splendors in building and interior display in the palace-like habitations of many a pagan, or uncivilized native, which would never have been deemed possible of execution by our own designers, however artistic their eye, or however deft their touch.

Processes and appliances for producing excellent results are known to many European workmen, in whose breasts the secret of such achievements is firmly locked. During the past few years many of these expert operatives in wood-carving have come to Canada, and their superior abilities have begun to manifest themselves in the wood manufacturing industry of this country, and latterly, to a very marked extent, so that a renaissance in wood-working may be fairly said to have resulted. The importation and employment of this class of talent led to a responsive sentiment in the the community, or such channels of it as evidenced a sufficiently refined or artistic taste to appreciate and encourage a sensible and utilitarian form of art, which was experiencing an important enhancement of its excellence, and now quite a pronounced stimulus has been given the industry of wood-work for house finishing.

Many of our native woods readily yield to the carver's tools and lend themselves to the artistic development of Canadian workmen, and many of our young native workmen have rapidly attained a state of proficiency as advanced as that of our foreign born fellow subjects.

The very finest workmen, especially those in the possession of some secret processes of doing difficult work, receive wages as high as $6 a day. The average pay of good wood carvers is from $3 to $4 a day. The process of ebonizing cherry wood, for instance is a secret known only to the workman who does it. Even the members of the firm in which he is employed have no right to ask what his secret is. The fact that he can get a finer, more ebony-like surface than any other man gives him a high value at once. Although the use of mechanical devices for carving wood are so much disliked by the best workmen, that sandpaper is forbidden, machinery is now used to cut away the rough parts of a bit of carving. A peculiar tool driven by steam power eats out the wood wherever it goes, and thus a skillful man blocks out in a rough way as much work in a day as 20 men could have done formerly.

The delicacy and lightness of wood carving, and the good pay which fair workmen receive for it, have already attracted many Canadian apprentices, who, untrammelled by union rules, are making rapid headway, and promise to surpass the foreigners.

Oak, cherry, birch, walnut and maple are the favorite woods used for interior finishing, oak and cherry being the most popular. The latter of these is now becoming very scarce, while there appears to be no limit to oak. Red oak, when properly finished, makes very handsome work and is quite popular in some localities. The heart wood of beech, when skillfully treated, has a beautiful appearance, and it is a matter of surprise that it is not more generally employed in hardwood finishings. Perhaps, when birch and maple get scarce, beech will have its innings.

BY THE WAY.

The expeditious manner in which the construction of the King Edward Hotel, Toronto, was pushed through by the contractors, Messrs. Illsley & Horn, has been the subject of much favorable comment. It is a subject for particular regret therefore that the firm have not been rewarded by a substantial profit, such as their energy merited. On the contrary they lost so heavily by the transaction as to be obliged to ask the indulgence of their creditors.

× × ×

Some of the persons who incite and engineer strikes of workmen as well as the workmen whom they represent, seem to be seriously afflicted with moral obliqnity. As an example, I would refer the reader to the case of one Samuel Parks, a walking delegate for the bridgemen's union of New York. Parks was arrested charged with accepting from the Hecla Iron Works the sum of $2,000, as blackmail for having agreed to call off a strike at the company's works, yet the bridgemen's union to whose interests Parks appears to have played traitor, is said to have re-elected him by a large vote as the union's walking delegate.

× × ×

Difficulty has arisen between the architect of the King Edward Hotel, Toronto, and the New York artist who designed and painted the mural decorations. The courts have been asked to grant an injunction to prevent any person other than the author of the paintings from making changes in them. The architect states that the panels were made too large for the spaces they were to occupy, and that in attempting to fit them in position the artist or the workmen deliberately cut the canvas, and in so doing mutilated the figures in the paintings. In an interview with a reporter the architect is reported to have said that the contractors for this work seemed to think that anything was good enough for Canada. The significance of this remark should not be lost upon Canadian architects who may be tempted to go abroad for skill which could probably be found at home. Some of our Canadian artists have done creditable work in the line of mural decoration, and the question is asked why was not the opportunity given them to submit sketches for these panels? It would have greatly added to the interest of this costly building if, as far as possible, it had been given a distinctively Canadian character, instead of being made a replica of the great hostelries of the United States. One of the charms to the traveller is to be brought into contact with distinctive national characteristics, as exemplified in architecture, social, customs, etc., differing from those to which he has been accustomed.

THE PORTLAND CEMENT INDUSTRY.

Up to the middle of the 18th century it was believed that the hardest hydraulic limes were made from the hardest and purest limestones. In the year 1756 Mr. John Smeaton, an Englishman, in course of certain experiments found that this was not true; that on the contrary hydraulicity was due to the presence of clay matter in the limestone.

A few years later this gentleman was entrusted to rebuild the Eddystone lighthouse. In this structure he used an hydraulic lime made by calcining a rock containing a certain percentage of clay material. So this beacon of the channel "stands to-day not only as a guide to ships that pass in the night, but also as a monument to mark the starting point in all that we know concerning hydraulic cement."

Three-quarters of a century passed and scarcely any advancement was made. Manufacturers and engineers seemed satisfied with the natural hydraulic cements. However, a surprise was in store. In 1824 Mr. James Aspdin, a brick-layer, of Leeds, England, reasoned: "If the degree of hardness and hydraulicity are proportional to the amount of clay matter present, why not add clay to limestone and calcine the mixture?" Experimenting along this line he hit upon a mixture which, burnt at a higher temperature and ground to a powder, formed, when mixed with water, a cement much harder than anything yet produced. Noticing strong resemblance in point of color and texture between his cement and the colitic limestone from the island of Portland, he named the former Portland Cement. He may also have been influenced by business reasons, because this Portland rock had for centuries been in favor as a building stone, being the material used in the construction of many famous public buildings, including St. Paul's Cathedral, London.

Following this a number of works were built in the Medway and Thames district, but, owing partly to the rule of thumb methods used in mixing the raw materials, and partly to crude and imperfect machinery, the products were seldom of the best quality.

The burning was done in a kiln not very unlike the ordinary lime-kiln we see in this country. It consisted of a barrel-shaped shaft about 35 feet high, and 10 feet at its greatest diameter. A few feet from the bottom were placed iron grates, and on these grates alternate layers, composed of coke and bricks of the dried mixtures, were dumped down from an opening near the top. This mass was fired at the bottom and allowed to burn itself out, which required usually three days. After cooling down, the residue consisting of underburnt material and clinker, was drawn off at the base and assorted. This kiln, with improvements tending towards economy, was used entirely until 1884, when Mr. Deitch patented a shaft-kiln which could be worked continuously. Since then other forms of continuous kilns have been built, each giving satisfaction on account of their economy. But the greatest advance came with the advent of the rotary kiln invented by Mr. Ransome, of England, in 1887.

For years England held a monopoly in cement manufacture and exported much. However, this was not to last. In spite of high walls built around the factories, foreigners grasped the secrets of the business.

The Germans, always true to their characteristic national method, which is to develop systematically and patiently the details of a general principle, made no exception of this case. The English had discovered that a superior cement could be made from calcium carbonate and clay; the German determined by chemical means the exact proportions required, and by using the calcimeter could gauge the mixture very closely before burning. They also discovered that a small percentage of plaster of Paris added to freshly ground cement had the effect of making it slow in setting.

Mr. LeChatelier, a Frenchman, in 1887, was the first to give the world a theoretical formula of the chemical composition of cement. He held that it consisted of a tri-calcium silicate together with a slightly variable amount of tri-calcium aluminate.

This stood until 1897, when Messrs S.B. and W.B. Newbury, of the United States, preparing silicates and aluminates of lime synthetically, found that cement was a mixture of tri-calcium silicate and di-calcium aluminate, expressed thus:—

$$X\ (_3CaO.\ SiO_2) + Y\ (_2CaO.\ Al_2O_3).$$

From this we deduce the formula that the percentage of lime = 2.8 × percentage of silica + 1.1 × percentage of alumina. This is the formula used by most cement chemists to-day as a standard for a well balanced clinker.

THE INDUSTRY IN THE UNITED STATES.

Before 1871 no Portland cement was made in America. In that year Mr. D. O. Saylor, of Coplay, Pa., who had been manufacturing a natural hydraulic cement, succeeded in making a low grade Portland cement by burning a mixture of pure limestone and argillaceous limestone which abounds in that locality. Since then Mr. Saylor and his successors have improved and enlarged their factories and to-day these mills along with thirteen others which have since been established within a circle of fifteen miles' radius, are producing a high grade of Portland cement at figures probably lower than anywhere else.

What is known as the dry system is used entirely here. The argillaceous limestone being a little low in lime has a small percentage of pure limestone added to it. The chemical composition of both ingredients is carefully determined, then after being measured in automatic weighing devices and intimately blended by being ground to an impalpable powder, the mixture is burned in rotary kilns.

The success reached by these manufactories in the Lehigh Valley broke the prejudice of engineers against the home-made article, and the demand soon grew greater than this region could supply.

A few factories were then built in New York and other states, but it was in Michigan that the industry was next to establish itself strongly. In this state nearly every lake and marsh rests on a substratum of marl. This is a soft, putty-like material consisting of nearly pure calcium carbonate. In Michigan the color is bluish, but in other places it is as white as snow. It was found that a mixture of this substance with clay could be effected and that the resulting slurry could be easily burned in rotary kilns so as to make a first rate clinker. Several works were at once erected, and although the operators at first saw many dark days in meeting the new conditions, they have ultimately triumphed. And to-day ten large plants turn night and day, during all but the coldest month, successfully producing a high-grade cement.

THE INDUSTRY IN CANADA.

In Canada manufacturers have been awake, and in spite of their being handicapped in respect of the item of fuel, the industry has grown within the last few years to such an extent that now Canadian factories can almost supply the Canadian demand. As yet the manufacture is limited to Ontario. In this province as in Michigan there are many beautiful deposits of marl and clay, so the wet process is used throughout.

Beginning at the west there are several plants located about Owen Sound. Some of these have met with a fair amount of success and have turned out a good quality of cement, but the systems used are more or less cumbersome and as yet no great quantities have been produced. Next year, however, a new plant situated at Durham is expected to reach a considerable output. This factory has nine rotary kilns. All the machinery is electrically driven by power generated from steam.

Farther east, at Lakefield, there was last year erected a plant of three rotaries. The works here are entirely driven by electricity furnished at a power house on the Otonabee River. The mill is small but very efficient and produces a good cement.

About ten years ago the Rathbun Company, of Deseronto, began manufacturing Portland cement at Strathcona. Here there is a large bed of pure blue clay. To this clay they added about 75 per cent. of marl which is brought by the Bay of Quinte Railway from Marlbank. Both these ingredients are very pure, and when properly mixed and ground were found to make a splendid cement. The burning was at first effected in intermittent kilns, but lately in continuous kilns. They now use one Deitch and two Calborgs. This company observed great care and at length produced a brand of cement that is not excelled anywhere. But as Strathcona is 40 miles away from the marl deposits and the system is rather expensive, the works here have ceased to grow. The heart of the industry in the Bay of Quinte district has been transferred to Marlbank, where the Canadian Portland Cement Company has lately built a most modern plant.

Near Marlbank there is a deposit of white marl averaging 97 per cent. calcium carbonate. This extends to about 35 feet in depth. Under it again there is a bed of soft blue clay varying from 10 feet to fifteen feet. It is thus seen that if nature did not intentionally plan the great manufactory now thriving there, she certainly made things very convenient, for there is no waste of raw materials.

The style of kiln now used in all modern plants in America is known as the rotary. It was invented fifteen years ago in England, by Mr. F. Ransome, who experimented in the Medway district with it. In his hands, however, it proved a failure, and in England the idea was abandoned. But a foreigner, this time an American, caught the idea and developed the details in such a way that to-day it is the best style of kiln extant, and during the last three years English engineers have been coming to America to learn the secrets of rotary kiln construction.

This kiln is a steel cylinder from 60 to 100 feet in length and from 5 to 8 feet in diameter. Mounted on roller bearings the kiln is slightly inclined with the horizontal. A large gear surrounding the shell about half way from either end, gives the kiln its motion. It has been found advantageous to have the gearing that drives the kiln connected with a variable speed countershaft by means of which the operator can vary the speed from ½ revolution per minute to two revolutions per minute. This kiln is lined with fire bricks to within 20 feet of the slurry end. This part is fitted with channel irons placed two feet apart and running parallel with the longer axis of the cylinder. At the elevated end a smoke-stack is built to carry off the waste gases.

At the lower and opposite end a 7 inch iron pipe enters through the centre of the hood. This pipe furnishes the kiln with fuel which at the present time consists of bituminous coal, dried and ground to a powder. The coal is prepared in a separate department. First it is conveyed from cars to rotary dryers, then crushed in crushers and ground in tubemills in which flint pebbles take the place of steel balls. From the tubemill it is conveyed to tanks with hopper bottoms, placed in front of the kiln. A screw conveyor driven by a speed regulator draws it from this tank dropping it into a syphon where an air blast drives it into the kiln. It burns immediately on entering the kiln, giving a temperature of about 3000° F. in the hottest zone which extends from 5 ft. to 25 ft. back.

The slurry which is pumped into the kiln at the elevated end slowly winds its way to the lower end. As the kiln revolves the slurry is carried up at first by the channel irons, and when a certain height is reached, it falls to the bottom passing through the hot gases which at first carry off the water vapor and later the carbon dioxide. After passing beyond the reach of the channel irons, it is dry enough to stick to the bricks till it reaches the top, and this operation is repeated once for each lineal foot the material travels. By the time it reaches the hottest zone it is thoroughly dried, but not completely calcined. In this zone the calcining is finished and a chemical combination takes place between the basic and acid elements of the semi-fused materials forming clinker. The clinker then rolls out of the hood in particles varying in size from a pin-head to a hickory nut. The advantages of this system of burning may be summed up as follows: (1) The slurry does not require to be dried and moulded into bricks before entering the kiln. This saves much labor, time and expense. (2) The burner has complete control of the process of burning. He has three variables at his command; he can vary the feed of the slurry, and coal, and also the speed of the kiln. By means of blue glasses he can see into his kiln from either end and watch the whole operation. (3) No raw material gets past the hot zone because the burner can distinguish the raw from the burnt, and when he sees raw material from the front end he adds heat or slows his kiln.

An objection is raised by a few to this system of burning. They hold that where so much coal is used to make the clinker, a great deal of ash from the coal must enter into the clinker. These persons lose sight of the fact that the greater part of the ash is silica and alumina, which acts as clay, and is in no wise objectionable, because it can be counteracted in the raw mixture.

However, we must admit that although the rotary kiln is the best kind known, it is still a very wasteful machine. In most mills the gases pass out of the smokestack at 1500° F., and the clinker passes out of the other end at a still higher temperature. Hence, at a glance one sees the tremendous loss of energy involved. Here lies the reason why too much coal is used. This fact is claiming much attention now and we may expect radical improvements soon.

ARTIFICALLY COOLING THE CLINKER.

The scheme, which is by no means satisfactory, but is looked upon as one of the best extant, is Mr. Mosier's system. This is installed at Marlbank. The Mosier cooler is a cyclinder 20 feet high and 8 feet in diameter. One is sufficient to cool the clinker from two kilns. It stands in front of the kilns, and as the clinker drops out of the kiln hood an elevator lifts it to the top of the cooler. It falls inside and strikes cones or discs which surround a cast-iron pipe running up through the centre. Cold air is forced out through openings in this pipe, and as the clinker falls from disc to disc it is cooled. At the bottom the cold clinker is drawn off into a dump-car, which is hoisted to large bins above the grinding machinery in the grinding department.

GRINDING THE CLINKER TO CEMENT.

Before the car of clinker is dumped into the bin above the ball mills, about 1½ per cent. of Plaster of Paris is added. If it were not the cement would, as before mentioned, be too quick in setting. The clinker is then fed into each ball-mill by an automatic disc feeder.

The finishing grind is done in No. 16 tubemills, lined with blocks of flint instead of blocks of wood. Flint pebbles are used here.

Every few hours samples of each mill's grind are sifted, and if there is more than 5 per cent. residue left on a sieve of 10,000 meshes per square inch, or more than 20 per cent. on a sieve of 40,000 meshes per square inch, the feed of the mill is reduced.

At the end of every twelve hours an average sample of the grind of that period is made into briquettes, having a section of one square inch. These are made by mixing cement with about 21 per cent. of water in the case of neat briquettes, and a less percentage where a mixture with sand is used. Two of these are broken at the end of 24 hours, during which time the briquettes have lain in moulds in a moist atmosphere. The remaining ones are then placed in water. Two more are broken in each of the following periods, three days, seven days, twenty-eight days, and three months, to determine their tensile strength, which must surpass standard specifications. A sample of cement made at Marlbank this summer taken at random, ran as follows:

1	day,	275	lbs. per square inch.
7	days,	630	" " "
28	days,	925	" " "
3	mos.,	960	" " "

From this same sample pats are made, which being set in moist air give the time of both initial and final set, and after being placed in steam for twelve hours, and then in water for the same length of time, prove by their condition at the end of the test whether or not the cement is sound.

All the leading Canadian manufactories go through this elaborate system of tests. Engineers need no longer entertain fears and doubts as to the quality of their work. Canada produces as good Portland cement as is furnished by any country in the world.—Percy F. Balfour, in Queen's Quarterly.

THE DOME.

Prof. Baldwin Brown recently read a paper before the Edinburgh Architectural Association in which he sought to vindicate the title of the dome to a place among the architectural forms suited to a Christian church. He pointed out that the main characteristic of the dome in general was its embracing, uniting quality, and said it was important so to employ it as to obtain from its full value as a unifying element in a composition. The employment of the dome as a mere roof, as in the multiplied domes of later byzantine churches, such as St. Mark's at Venice, or the series of cupolas along a rectangular aisle, as in churches of the West of France, was not the way to secure all the advantages of that most beautiful and expressive feature. The dome, wherever it appeared, lent distinction to a building, and it had been rightly pronounced to be on the whole the most satisfying to the æsthetic sense of all architectural forms. The real power of the dome was, however, only exhibited when it was made to exercise an influence far beyond the limits subtended by its own circumference, and brought into harmony the complex elements of a subdivided plan. The pantheon of Hadrian at Rome, the starting point of the development of dome construction in the modern world, completely embraced the spaces of the plan it surmounted, but this plan was that of a regular unbroken circle. The Christian builders desired to use the dome for their own purposes; but such a plan as that of the Pantheon was not suited for a Christian meeting-house. One of the most interesting chapters in the whole history of architecture was occupied with various experiments made by early Christian architects to adapt the dome to plans suited to the requirements of congregational worship. Their efforts to overcome the difficulties which presented themselves were sufficient proof that they recognized the dome as a form not only beautiful in itself, but expressive of Christian ideas, and this was a consideration too often lost sight of by the Mediævalists of to-day, who, as the discussions connected with the new Liverpool Cathedral had shown, were still dominated by the ideas embodied in the Gothic revival of the first half of the 19th century.

ARCHITECTS' FEES IN RELATION TO FIRE INSURANCE.

It would seem to require no argument to show that when appraising the owner's loss on a burned or partially burned building the insurance companies should include architects' fees, which item entered into the original cost of the building upon which the insurance is based In Canada this item is included in the owner's claim and is allowed by the insurance companies, but in England there appears to be no recognized practice with regard to this matter.

Enquiry has recently been made by Mr. T. Myddleton Shalcross about the practice of eighteen or twenty of the principal British fire insurance companies in respect to the payment of architect's fees. He has ascertained that some of the companies refuse to pay architect's fees incurred in the reinstatement of fire damage, notwithstanding that premium has been paid upon architect's fees, originally incurred, as part of the cost of the building insured; that other fire insurance companies only pay fees in cases where they have been

separately mentioned and described in the policy; and, again, that other fire insurance companies always pay such fees whether or not they are separately described in the policy. Those who think they are insured against fire would do well, therefore, says Mr. Myddleton Shalcross, to inquire from their assurers how the matter stands in their own particular cases, as otherwise, should a fire occur, they may find themselves uncovered to the amount of several hundreds of pounds in respect of their premises. For example, in the case of a building costing, say, £10,500, including architect's fees, and totally destroyed, the owner might find himself only able to recover £10,000, and have to bear the loss himself of the remaining £500, or, in the alternative, have to be satisfied with an inferior class of work in the reinstatement of the premises, i.e., work performed at the will of a builder without the direction and control of an architect, and there would, of course, be a similar result in case of a partial destruction of the premises pro rata.

ABSORBENCY OF CLAYS AS AFFECTED BY DRYING.

Mr. H. J. Cambie, in a paper recently read before the Canadian Society of Civil Engineers, gives the results of a curious and important observation upon clays. It appears that a portion of the Canadian Pacific Railway passes through a valley almost without rainfall, through the bottom of which flows the Thompson River. Above the river are high clay bluffs, forming the edge of a sort of table-land, some 200 ft. above the river. When irrigated, this clayey table-land is fertile, producing several crops of hay a year, and the farmers utilize it for that purpose, irrigating it with water from the river or its tributaries. Since irrigation of the land began, some forty years ago, there have been many land-slides. One of these, a few years ago, carried a tract of about a hundred acres directly across the river, forming a dam 75 ft. high, and completefy blocking its course; and another recently damaged the railway. In consequence of the latter, suit was brought by the railway company to prevent the farmers from irrigating their fields, on the ground that the irrigation softened the clay subsoil, allowing the ground to slip. This view was confirmed by experiment, the experts, of whom Mr. Cambie was one, finding that while ordinary clay, in the moist condition in which it is usually found in the ground, will not absorb any more water, and is only superficially affected by washing, clay that has once been so completely dried as to lose its cohesive property absorbs water like a sponge until some 60 per cent. of its weight has been added, when it falls into a liquid mud, nearly as fluid as water. Even when the clay has not become powdery by drying, but has taken the form of indurated lumps, it will soak up the water until converted into fluid mud. As the clay of these hayfields exists, to a great extent, in the form of such dry lumps, it seems probable that copious irrigation through the season might liquefy it, so as to allow the ground to slide; while the objection that the clay on the immediate bank of the river was not affected appeared to be answered by the fact that this clay, being constantly kept moist by the water of the river, preserved its solidity.

A COLOSSAL STRUCTURE.

Mr. McKim, the well-known architect, is said to have designed a Stadium of larger area than the Colosseum at Rome, to be erected on the athletic field at Harvard College. This structure will resemble a continuous stand following the two long sides of a football field and one of the short sides. The length of the arena enclosed will be no less than 450 ft., and the extreme length of the whole building as viewed from the road that crosses Harvard Bridge will not fall far short of 200 yds. In other words, the stadium will be about equal to the Colosseum in length, but will afford a larger arena. The plans of the Harvard stadium show a design as remarkable for simple elegance as for constructive ingenuity and economy. The frame work will be of iron girders, the facing of concrete blocks. The vast iron skeleton within will be entirely concealed under a mask of yellow white that will present, with practically the same effect as solid stone, all the familiar aspects of a Roman amphitheatre. Tier upon tier of seats will rise to a height of 100 ft., affording seats for 24,000 spectators on ordinary occasions, for 40,000 in an emergency. Behind and above the topmost row will run a roofed gallery supported on light pillars; this is designed to provide a sheltered promenade and to give a necessary architectural finish to the building as seen from within.

The exterior aspect of the stadium will be on lines that the form of the interior makes inevitable. A colonnade of three super-posed galleries surmounted by a heavy cornice, unadorned by superfluous embellishment, will give simplicity and severity to the outward aspect of the building. The height being about two-thirds that of the Colosseum, the massiveness of the piers, or rather of the appearance of the piers, will also be somewhat less.

NOTES.

The Royal Institute of British Architects have this year awarded the King's gold medal to Mr. Charles F. McKim, a distinguished architect of the United States.

Mr. R. F. Gagen, of Toronto, and Mr. Wm. Hoper, of Montreal, have been appointed Commissioners to get together as representative collection as possible of paintings by leading Canadian artists, living and deceased, for the approaching Dominion Exhibition in Toronto.

An Act has just passed the Prussian Parliament which empowers local authorities to forbid any form of conspicuous announcement that impairs the landscape or any placarding of private premises whether relating to the premises conducted therein or not. The Legislature of the state of Massachusetts has passed a similar Act. So far as known no legislation on this subject has yet been enacted in Canada, but it is to be hoped that on this important subject public opinion here will not lag behind that of Great Britain, Germany and the United States, all of which countries have recognized and sought to abate the evil. Unfortunately the mischief which such legislation aims to prevent has already to a large extent been done, as witness the glaring announcements on barns, etc., on the principal lines of travel all over this continent. Particularly is the evil manifest on the outskirts of towns and cities.

According to the Engineering Record over-exposed blueprints can, in many cases, be restored by immersing them in a bath of weak ammonia, using about two spoonfuls of ammonia to a tumblerful of water. This will cause the print to turn first purple then pink and after a time nearly white. When it has reached the pink stage, rinse the print and immerse in a bath composed of water, 1 tumblerful, muriatic acid, 1 teaspoontul. The blue color will then return much brighter than before, but this time the lines will be white and clear. Wash thoroughly before drying. Stains on tracings caused by blueprint water can, also, be removed, according to the American Machinist, by painting the spot with a camelshair brush dipped in a 10 per cent. solution of oxalate of potash. This same solution may be used for making white lines on blueprints. Almost any alkali will bleach a blueprint, but this solution will turn the blue to a pure white.

PROPOSED STANDARDS OF FIRE RESISTANCE.

The executive of the British Fire Prevention Committee, having given their careful consideration to the common misuse of the term "firepoorf," consider the term "fire-resisting" more appicable for general use, and that it more correctly describes the varying qualities of different materials and systems of construction intended to resist the effect of fire for shorter or longer periods, at high or low temperatures as the case may be, and they advocate the general adoption of this term in place of "fireproof."

Further, the executive, fully realizing the great variations in the fire-resisting qualities of materials and systems of construction, consider that the public, the professions concerned, and likewise the authorities controlling building operations, should clearly discriminate between the amount of protection obtainable or in fact requisite for different classes of property. For instance, the city warehouse filled with highly inflammable goods of great weight requires very different protection from the tenement house of the suburbs.

The executive are desirous of discriminating between fire-resisting materials and systems of construction affording temporary protection, partial protection, and full protection against fire, and to classify all building materials andsystems of construction underthese three headings. The exact and definite limit of these three classes is based on the experience obtained from numerous investigations and tests, combined with the experience obtained from actual fires, and after due consideration of the limitations of building practice and the question of cost.

The executive's suggested minimum requirements of fire-resistance for building materials or systems of construction will be seen from the standard tables appended for—I. Fire-resisting floors and ceilings. II. Fire-resisting partitions. III. Fire-resisting doors, but they could be popularly summarized as follows: (a) That temporary protection implies resistance against fire for at least three quarters of an hour. (b) That partial protection implies resistance against a fierce fire for at least one hour and a half. (c) That full protection implies resistance against a fierce fire for at least two hours and a half.

The conditions under this resistance should be obtainable, the actual minimum temperatures, thickness, questions of load, and the application of water can be appreciated from the annexed tables by all technically interested, but for the popular discrimination which the executive are desirous of encouraging—the time standard alone should suffice.

It is desirable that these standards become the universal standards in this country, on the Continent and in the United States, so that the same standardisation may in future be common to all countries, and the preliminary arrangements for this standardisation are already in hand.

STANDARD TABLE EOR FIRE-RESISTING FLOORS AND CEILINGS.

Classification.	Sub-Class.	Duration of Test at Least.	Minimum Temperature.	Load per Superficial Foot Distributed.	Minimum Superficial Area under Test.	Minimum Time for Application of Water under Pressure.
Temporary protective class	A	45 mins.	1500° F.	Optional	100 sq. ft.	2 mins.
	B	60 mins.	1500° F.	Optional	200 sq. ft.	2 mins.
Partial protective class....	A	90 mins.	1800° F.	1 cwt.	100 sq. ft.	2 mins.
	B	120 mins.	1800° F.	1½ cwt.	200 sq. ft.	2 mins.
Full protective class.....	A	150 mins.	1800° F.	2 cwt.	100 sq. ft.	2 mins.
	B	240 mins.	1800° F.	2½ cwt.	200 sq. ft.	5 mins.

STANDARD TABLES FOR FIRE-RESISTING PARTITIONS AND SINGLE DOORS, WITH OR WITHOUT FRAMES.

Classification.	Sub-Class.	Duration of Test at Least.	Minimum Temperature.	Thickness of Material.	Minimum Superficial Area under Test. For Partitions.	Minimum Superficial Area under Test. For Doors.	Minimum Time for Application of Water under Pressure.
Temporary protective class.	A	45 mins.	1500° F.	2 in. and under	80 sq. ft.	20 sq. ft.	2 mins.
	B	60 mins.	1500° F.	Optional.	80 sq. ft.	20 sq. ft.	2 mins.
Partial protective class.	A	90 mins.	1800° F.	2½ in. & under	80 sq. ft.	20 sq. ft.	2 mins.
	B	120 mins.	1800° F.	Optional.	80 sq. ft.	20 sq. ft.	2 mins.
Full protective class	A	150 mins.	1800° F.	2½ in. & under	80 sq. ft.	25 sq. ft.	2 mins.
	B	240 mins.	1800° F.	Optional.	80 sq. ft.	25 sq. ft.	5 mins.

FAILURE IN A BUILDING CARRIED ON COLUMNS.

Some interesting and instructive data are given in the appendix to a recent report by Sir Wm. Garstin of the Public Works Department of Egypt regarding the failure of a four storey prison building in Cairo, and the method employed to repair the same. The ground, first, and second floors provide accommodation for 250, and the third floor for 200 persons. The corridor-wall of the top floor is carried by two cast-iron columns, one above the other, having a total height of 35 feet 6 inches, and transmitting a load of 58 tons to the stone base of the columns. The building is founded on a float of pozzuolana concrete, 4 feet in thickness, laid at permanant infiltration level. This form of foundation was adopted because the excavation showed that the whole area covered by the foundations had at one time been a deep depression which, many years previously, had been filled up with earth, stones, and rubbish.

The infiltration water prevented the excavation being carried any deeper to get to the virgin soil. As there are no cracks in the outer walls of the building, it may be assumed that this float of concrete is intact.

Soon after the completion of the building, cracks appeared in the brick cross-walls of the top storey. Starting at floor-level, where this wall rests on the corridor-wall below, the cracks followed a straight line drawn from this point to a point where the ceiling meets the corridor-wall of the top storey, which is carried on the columns.

These cracks were evidently caused by the columns settling, and on investigation it was found that the base-flanges of some of the columns were cracked. On stripping the asphalt off the stone bases these also were found to be cracked, and the failure was therefore attributed to the crushing of the stone. It appeared also that the base-stone had been dressed hollow, which would have the effect of throwing the pressure on the outside of the base-flange, and would account for its being cracked. It was further observed that the stones were saturated with damp, which made them soft. This was the result of the water used in swabbing down the ground floor finding its way to the stone, through the joint between the asphalt and the cast-iron column. By calculation it was found that the base-stone, which was of limestone and measured 2 feet 8 inches square by 1 foot 6 inches in depth, was overloaded, as it was exposed to a pressure of 590 lbs. per square inch, whereas ordinary samples of this stone are crushed at a pressure of 3,000 lbs. per square inch, giving a factor of safety of only 5. This explanation of the failure was not very convincing. That the stone should have crushed when only loaded to one-fifth of its laboratory crushing-strength, even although it was weakened by being saturated with damp, seemed doubtful. New stones 3 feet 6 inches square by one foot 6 inches in depth were ordered from Trieste, and new columns from England. Tripod shores on wide timber bases were erected round the columns, and gypsum tell-tales showed that the movement continued. Much deliberation was given to deciding on the best means of supportiug the superstructure (a load of 58 tons) while the thirteen columns and base-stones were changed. No risks could be run which would endanger the lives of between 400 and 500 people who inhabited the building. The result of this forethought was so satisfactory that during the work no change was found necessary either in shoring or in the method of working.

The shoring consisted of a pair of A-frames set up under the girder carrying the gallery at first-floor level. Their feet were let into timber bed-plates, 2 feet 4 inches by 1 foot 2 inches, with a tightening-wedge under each foot. These wedges were especially useful in loosening the shoring before removing it. Under the bed-plate and directly below each foot were inserted iron folding-wedges working between iron plates. The lower plates rested on a bed of cement concrete 12 feet by 12 feet by 3 feet 6 inches in thickness. This bed of concrete was necessary to distribute the pressure, all of which came on new filling, 10 feet in depth between the concrete foundation and the bottom of this concrete. The pressure on the earth was thus reduced to less than ½ ton per square foot.

The longtitudinal rolled joist (1 foot 2 inches in depth) at the first-floor level not being stiff enough to carry the weight between the A-frames when the column was removed, Iron joists which bore on the A-frames were packed in under the flanges of the saddle-piece between the upper and the lower column. Also vertical shoring with tightening-wedges was carried up to main girder carrying the top-story corridor-wall. The upper columns were thus relieved of their weight during the operation. All the shoring was braced across the building and tied to the main walls. To avoid vibration as much as possible in tightening up the wedges when transferring the load to the shores, two 50-ton hydraulic jacks were set up between the A-frames and the base-stones. These took the first lift. A piano wire was stretched between the main walls, touching the columns, to enable the vertical movements to be recorded.

On excavating to put in the cement-concrete for the first column, the cracks in the base-stone, which were little more than visible on the surface, were found to be wide enough at the bottom of the stone to allow of the insertion of the fingers of the hand up to the palm. Wrought-iron straps were quickly fixed round the stones to prevent them opening further, and shoring was erected under the longitudinal girder of the first floor at the edge of the pit. A boxing of 1½-inch boards was made round the pit, to prevent the earth-filling from falling in while the concrete was being rammed. The concrete was allowed to set for 7 days before the shores for changing the columns were erected. When all was in place the wedges on the first and second floors were driven hard with a sledge-hammer. The jacks were then worked until a slight rise (1/32 to ⅛ inch) was observed on the wire. The iron folding-wedges under the A-frames were then driven hard. Stone-cutters with chisels then cut away 1 inch clearance under the column, which was thus left suspended by the bolts of its upper flange. The jacks were next slacked, when a drop of 3/32 inch to 3/16 inch* occurred. After a short pause to let the shores settle down to the weight, the rest of the base-stone was cleared.

The main cause of the failure was then discovered. The stone had been levelled by means of wooden wedges, which were left in place, and had been grouted with pozzuolana mortar. The grouting in some cases had not even touched the underside of the stone at the centre, and in all cases the bed was found to be hollow, so that the whole weight was supported on the wedges and an outer margin of about 6 inches in width where the mortar could be rammed under with a trowel. Consequently the stone had broken into four pieces. There was not much evidence of what might strictly be called crushing, and the dip of the stone in breaking and settling into the hollow gave the appearance which was attributed to faulty dressing, and accounted likewise for the flanges of the column becoming cracked.

The old base-stone having been cleared, the old column was removed, and, in order to provide clearance for getting in the new stone and column, the top course of the rubble masonry under the stone (about 6 inches in depth) was demolished. The new Trieste stone base was then slung into place, by means of a lewis and differential blocks, without being set, and was left about 6 inches below its ultimate level. The new column was then slung and bolted up permanently into its place. A wrought-iron plate, 1 inch thick and planed on its upper face, was laid between the stone and the base of the column. The stone base was next raised on wooden wedges so as to leave only ⅜ inch to ½ inch clear below the column. After the stone had been levelled, a grouting basin in brick masonry in cement was built round it, at a little distance from it, the walls being 8 inches higher than the bottom of the stone. Neat cement grout was introduced under the centre of the stone by means of a 2-inch pipe. The grout was under a head of 4 feet or 5 feet. In this manner the space under the centre of the stone ought to be as well filled as any part. By having a head on the grout a flow was established from the centre to the outside of the stone, which carried with it the air and cement scum. The basin was filled up by this means, thus throwing 8 inches head on the grout, which allowed the water in excess to rise to the surface. The horizontal portion of the pipe was not withdrawn.

Thin steel wedges were used to force the wrought-iron plate against the base-flange of the column, and the ⅜-inch space under the plate was grouted with neat cement under about 4 inches head. After setting for 7 days, the wedges under the stone, as well as the steel wedges, were withdrawn, and the shoring was removed. The drop on removing the shoring varied between nothing and 3/32 inch. The greatest collective drop on any column, adding all the movements together, was less than ¼ inch, the mean drop of the thirteen columns being 5/32 inch and the least drop 3/32 inch.

*These figures represent the maximum and minimum observations taken on the thirteen columns.

NOTES.

In setting cut stone work in England lime mortar only is used. Cement is never used for that purpose, as it stains the stone.

Flatted work will sometimes require a coat of size before gilded work is put upon it, as at times there is a little suction. This would draw the size and cause imperfect gilding.

The City Engineer of Winnipeg has submitted an estimate to the city council for the construction of a railway connecting Winnipeg with the city quarries, at a cost of $138,425.

The report of the building inspector shows that in proportion to size, Westmount's activity in the building line has been more marked than that of Montreal.

The assets of the Holywood Paint Company, of Hamilton, have been purchased by the McLennan Paint Company, Limited, of Buffalo, who will continue the business.

Instead of the iron fireproof curtains generally used in French theatres, one made of sheet aluminium has been adopted for the opera house at Besancon. It is one-fifth the weight of an iron curtain of equal dimensions.

Dr. J. M. Woodbury, commissioner of street cleaning in New York, proposes to manufacture paper bricks from the dry city rubbish, of which 90 per cent. is waste paper. These bricks are intended for fuel and Mr. Woodbury estimates that private consumers could purchase them for 4 cents a cubic yard.

A meeting of the Executive Committee of the National Master Painters' Association of the United States and Canada, was held in Toronto in the early part of last month, to consider arrangements and outline the programme for the annual convention, which will meet in Toronto next February. A very interesting meeting with a large attendance is looked for.

A machine for splitting laths for plaster work has been introduced in Great Britain. It is said to turn out in a day as many laths as would in the ordinary course be produced by 20 skilled men. The advantage of split as against sawn laths is said to be that they are tougher (following the grain) and have a rougher surface, so that plaster adheres more firmly.

The launching of new cement manufacturing companies in Canada goes merrily on. Hardly a month passes without witnessing the granting of charters to new companies in this line. In every case, if we may believe the statements of the promoters, there is going to be millions in it for the stockholders, but our opinion is that if the manufacturing capacity continues to increase at anything like the ratio witnessed during the last two years, there will soon cease to be a fair profit in the business for anybody. Admitting that the demand for cement has increased at a truly wonderful rate, it is nevertheless being outstripped by the growth in manufacturing capacity.

The master and journeymen carpenters of Halifax agreed to submit their differences as to scale of wages, to a board of arbitrators composed of the County Judge, the President of Dalhousie College and a representative of the Trades and Labor Council. The arbitrators have concluded that 25 cents an hour be paid to first-class workmen only, the men to be entitled to the new scale of wages from the first of June. The decision as to who are first-class workmen is to rest with the foremen of the several firms who, it is agreed, shall not be members of any union. The day shall be nine hours, and all who cannot rate as first-class men are to receive the old rate of 12 cents per hour. The dicision has been accepted by all parties concerned.

Nothing probably has exasperated the average architect more often or more thoroughly than the average mill company's book of stock designs of doors, mouldings, balusters, railing, newels, etc. Just why it is necessary to turn out such abominations, when it would not cost them a cent more to produce something along correct lines, artistically speaking, is one of the unsolved problems of the day. Did they but realize that these things all have their legitimate effect upon the public taste, especially those who seldom rub up against architects, possibly they would revise their books and get out something equally pleasing to the critical taste of the architect and the untutored ideas of their customers, who must certainly be easily pleased, judging by the stuff they continue to buy and use.

In answer to a correspondent the Painters' Magazine says it depends to a great extent on the composition of the plaster as to whether a new or "hot" wall can safely be painted. We have seen walls that were painted in less than two weeks after being finished, and yet with only two coats of lead, zinc and oil paint they did not spot or streak in the least. A wall that we do not know anything about is always safest to paint after a year or so, but as people will not wait, it is best to take the precaution of giving a coat of strong vinegar direct to the plaster. Let this stand two days, then prime with pure lead and raw linseed oil, adding a trifle of japan. Over this, when dry and hard, give a coat of glue size, which will save at least one, probably two coats of paint and will prevent spotting or discoloration.

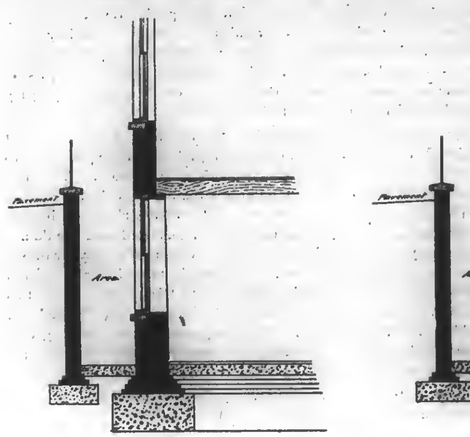
The Iron Age is authority for the statement that, with the same number of hours per day and the same rate of wages, the erection of steel framework in New York costs from two and a half to three times as much as in other cities which are also supposed to be cities of high building costs. It is stated that a hand riveter who could easily average 250 to 300 rivets a day contents himself in that city with 80. In other cities, on straight work, a good man finishes up 80 an hour. The pneumatic riveter, which has proved such an annihilator of time in other cities, finds something different in the air of New York, and strikes a slow gait. The same tool in the hands of a man elsewhere will drive 1,500 to 2,000 rivets in a day, and only 250 to 300 in New York. The claim is, in fact, made that structural erection in New York costs $15 to $18 per ton, against $6.50 to $8 per ton in other large cities. This is a "condition and not a theory," and must be faced alike by employers and by the men themselves.

Tensile tests of wrought iron bars, showing the effect of overstraining followed by intervals of rest, were made at the Watertown Arsenal upon four kinds of wrought iron: Common Refined, Best Puddled, Burden's Best and Norway. One test on each kind was made in the ordinary manner. With the other specimens an overstraining load was applied, ranging from 25,000 to 45,000 pounds per square inch, followed by an interval of no load, after which the loading was resumed until rupture was reached. The gain in the elastic limit produced by the overstraining loads was well shown throughout the series, and ranged from 2,000 to 6,000 pounds per square inch. It was also apparently shown, although these effects are not so well marked, that the greater the magnitude of the overstraining load and the longer the interval of rest between the two loadings, the greater was the gain in the elastic limit. No effect of the overstraining load upon the contraction of area was apparent.—Engineering Record.

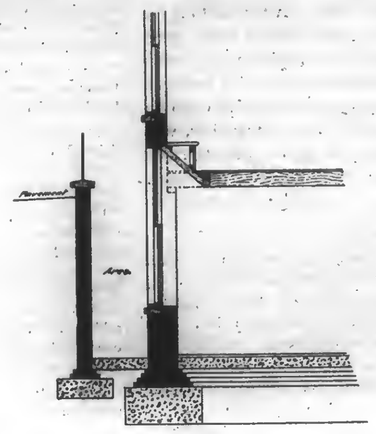
NATURAL LIGHT TO BASEMENTS.

An inexpensive means of providing additional light to a basement room is given in the sketches accompanying this article by B. Wand, reprinted from the Builders' Journal. Fig. 1 shows a basement room abutting upon an area and looking out upon a dead wall. The ceiling-line of this room is practcially level with the pavement, and in the figure the window is kept to its full height—at a height which would, as a matter of fact, necessitate the threading of a short length or rolled steel joist, or some other contrivance, through those ends of the floor joists which run above the window openings.

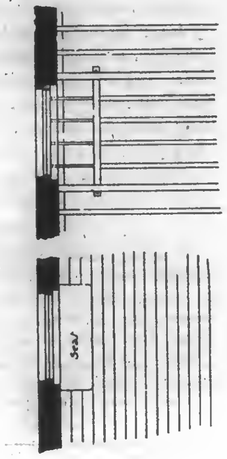
In Fig. 2 is shown precisely the same room, area and wall, but with the window carried well above pavement-level, and giving the room a very considerable increase of natural light. The floor-joists are trimmed at the window openings just as they would be for a fireplace, the trimmed space being filled in with pieces of 3in. by 2in. or other light stuff to carry the lathing and plaster or matchlining with which the soffit is to be covered. Fig. 3 shows (a) the trimmed space with filling-peices



—Fig. 1.—



—Fig. 2.—



—Fig. 3.—

— Scale of Feet —

and (b) the floor when laid. The objection to this mode of dealing with a floor has been that small bulkheads are formed over those portions of the floor beneath which come the basement windows; and this is met in my plan by the provision of window seats, which in their turn entirely cover the bulkheads. It may still be objected that these window seats would in themselves be unsightly; but when I say that I have seen them just as described in one of the finest block of flats in London—Albert Court, Knightsbridge —I think that that contention also is met. As a matter of fact, neatly panelled, and finished to match the other work in the room, they form quaintly attractive features, which the tenants contrive to render still more attractive by rugs, cushions and general "drapery."

In the plan I have shown the trimming is applied to a floor with wooden joists running from front to back of the building; but with joists thrown across, or with concrete or any other kind of floor, the idea is just as easy of adoption. In the case of shop property the bulkheads might not be objected to, or, if they were, countering or show-casing might take the place of the window seats. Where an area is covered with pavement lights the same idea is practicable so long as the lights are on private ground and no objection is made by the local authority to their being raised to a level with the added height of the windows. They could then be thrown back at an angle from window head to pavement level, or built square out from the head with a return to pavement level, the prisms being arranged to throw the light right back into the room; and, either way, a considerable increase of light would be obtained.

SANITARY CHARACTERISTICS OF MADE GROUND.

Architects and house owners should be interested in learning the results of an investigation recently conducted by Dr. W. G. Savage and Mr. J. H. Sugden, bacteriologists for the Corporation of Cardiff, Wales, to determine to what extent made ground should be regarded as a menace to the health of the occupants of houses built thereon, and how far local authorities are justified in passing by-laws prohibiting the use of such ground as building sites. The following deductions are made based on a long and careful examination :—

"The refuse as deposited contains a very large number of organisms, many of which are in the main different from those met with in ordinary soil. These made-soil organisms, as they may be called for convenience of reference, rapidly diminish in number under the conditions under which they are placed. This diminution goes on for the first two or three years. After two or three years, however, the ordinary soil organisms begin to invade this material, and apparently thrive abundantly in the rich organic material available to them. This causes a marked increase in the total number of organisms present in the soil, and the total number remains large, until in quite old soils a diminution is again met with. These soils begin to lose their special bacterial content after two or three years, and from that time begin to take on the characters of ordinary soil."

NOTES.

One of the features of the modern house that makes or unmakes its finished elegance is the plumbing and all care and attention given to that branch of the house will prove profitable. So rapid have been the strides toward betterment in plumbing fixtures during the last few years that not everyone is familiar with the high grade sanitary appliances which are sold to-day. The James Morrison Brass Manufacturing Company, Limited, of Toronto, have for years been the designers of many of the improved appliances used by plumbers and their line of equipment for every purpose to-day represents the highest attainment in manufacture. Anyone who is interested in modern plumbing would find the catalogue of the Morrison Company of interest and value.

Dr. ROBERTSON, President. J. S. McCANNEL, Managing Director.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and change of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUN EMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

NOTES.

The demand for hand-molded brick is increasing in the East. The machine-made brick now sells at from $6 to $7 per thousand while the hand-molded brick readily bring $10 a thousand. Many brick yards are adding to their hand-molding facilities. It is contended that machine-made brick chip easily at the corners and disintegrate more readily under the action of fire when used for furnaces and boiler linings than the hand-molded product.—Brick.

Grand Stands.

The return of the football season should act as a reminder to architects and builders as well as municipal authorities, that the lives of many hundreds of spectators will depend on the knowledge of those who design grand stands and the honesty of those who build them. Following the disaster on the football field at Glasgow last year, comes news of the recent collapse of one of these grand stands at Perth, Scotland, resulting in serious injury to thirty persons.

Plainness in Design.

Less than two years ago we took occasion in these columns to deplore the cheap and meaningless ornament with which most of the furniture manufactured in the United States and Canada was being overloaded, and the consequent perversion of the public taste. It is gratifying to observe that in the short period that has since elapsed, there has taken place a radical change in furniture design, with the result that plainness is now the leading characteristic. The change is a most agreeable and wholesome one, and will be certain to have a beneficial effect on architectural design and furnishings. It would be interesting to learn what have been the principal causes which have brought about within so short a time so complete a revolution in popular taste.

The Commercial Congress.

The important bearing of commercial interests on national affairs and policy was well illustrated by the keen interest manifested throughout the Empire in the deliberations of the Commercial Congress held last month in Montreal. There is evinced a strong desire on the part of the various colonies and some of the leading British statesmen that the various parts of the Empire should be more firmly welded together. It is realized that one of the best means to this end is by promoting closer trade relations. A step in this direction was taken by the Commercial Congress in adopting a resolution affirming the desirability of this object and recommending the Imperial government to appoint a special commission to make thorough enquiry into the matter and make such recommendations as in its judgment might seem wise and feasible. The subject is of the highest possible importance to each constituent part of the Empire as well as to the nation as a whole. The

British government should lose no time in appointing a Commission capable and willing to give it prompt and careful consideration. The national life of the people of Canada, in all its varied relations and aspects must necessarily be largely influenced by those with whom we have most intimate trade relations. Therefore should not this question of our future trade relations possess an interest for architects, builders, and indeed citizens of every class ?

The Slate Industry.

Several years ago one of the few slate quarries then in operation in Canada, was closed down because a profitable market could not be found for the output. The Canadian market had been made a dumping ground for the product of United States quarries, for which there was not sufficient home demand, and prices were cut so close that there was no money in the business for anybody. Now the conditions are very different. The United States market largely absorbs the output of the quarries, and British importers who formerly got their supplies from that source are trying to buy in Canada. This would therefore seem to be a favourable time to revive the manufacture of slates on a larger scale in this country and especially in view of the assured increase in the home demand arising from the rapid growth of our population.

The Dominion Exhibition.

The extensive and interesting display of natural and manufactured products of all kinds shown at the Exhibition which has just closed in Toronto, taken in conjunction with the great improvements made to the buildings and grounds fully warranted the more ambitious title of Dominion Exhibition employed by the management this year. From an architectural standpoint the Exhibition has been rendered much more satisfactory by the erection in permanent material: of a number of well designed buildings, such as the Art Gallery, Manufacturers' Building, Stove Building, etc., and the removal of many small structures which gave to the grounds a crowded appearance. With these out of the way the grounds convey an impression of spaciousness which greatly enhances the appearance of the principal buildings and satisfies the eye. The Stove Building, a substantial brick structure, has already proved inadequate for its purpose. While there was an exceptionally good display of heating apparatus by the various Canadian manufacturers, the exhibit would have been still more representative had the necessary space been available. It seems unfortunate that in planning this building provision was not made for the larger requirements of the future.

In keeping with the permanent character of the new buildings, the exhibits were on a larger and more varied scale than ever before, and received greater attention from visitors. The exemplification of manufacturing processes was a new and instructive feature, and the high quality of the finished products marked "made in Canada," should tend to dispel the too largely prevalent notion that for goods of the highest quality one must purchase from foreign makers. The expense and care bestowed on the arrangement of the exhibits is deserving of praise and gave to this year's Exhibition a refinement in pleasing contrast to the crude results of earlier efforts. In this respect we have no doubt learned profitable lessons from the larger exhibitions in the United States. It is gratifying to know that we have reached a point in our national development where there is demand for beauty as well as utility. This demand is likely to be stimulated by a sight of the many beautiful examples of artistic workmanship comprising the collection of Jubilee presents, the loving tribute to Queen Victoria from her subjects in all parts of the Empire. The Canadian people are under a debt of gratitude to King Edward for the kind consideration which prompted him to allow this valuable treasure to be brought to Canada and placed on public exhibition. The enterprise of the exhibition management in securing such an interesting feature is also deserving of recognition.

Building Conditions

The recently published statement showing the value of building operations in Toronto for the first half of the present year to be considerably in excess of the corresponding months of last year, came as a surprise even to persons most closely identified with the building industry. The opinion prevailed that owing to the long continued strikes the showing would be a bad one. The great scarcity of houses for rent in Toronto has compelled many persons to build, notwithstanding the high cost, and has induced a considerable amount of speculative building of houses of a fairly substantial character. It is in this direction that the greatest volume of building has been done this year. Apart from a number of new factories very few important buildings of a commercial or public character are in process of construction. The high prices of materials and labor coupled with unsettled labor conditions in Toronto led to the abandonment for the present of several costly undertakings. One regrettable feature of the situation is that owing to changed conditions some of these projects may never be carried out. In Montreal as in Toronto the demand for houses is very active, with corresponding activity in building. The suburban real estate sold during the month of July amounted in value to $180,989 and in the city proper to $732,838. The value of building permits for the month named was $533,247. Reports from Winnipeg and other cities indicate that the building operations will probably exceed those of any previous year. Satisfactory as are the existing conditions, reflecting a high state of prosperity, they would have been much more so, had it not been for the uncertainty and delay caused by labor troubles.

It has been estimated that the aggregate cost of large buildings in South Africa now in process of construction or under consideration is about $100,000,000, one half of this amount being for government work. The general tendency is not to be sparing as to the additional expense necessary to insure stability and comfort by the adoption of the most approved modern systems. A suggestion has been made for the establishment by English manufacturers of central depots at Cape Town and Durban, where stocks of heavy building materials would be carried. In the present state of affairs in South Africa there is a marked preference for constructional supplies available for immediate delivery. The results of similar arrangements in other branches of trade seem favorable to the development of this new project.

NOTES OF TRAVEL.—IV.

The Guild of Handicraft.

An actual, practical, going concern, devoted to handicraft as opposed to machine workmanship is worth visiting, and, as the new home of the Guild of Handicraft came by my way, I turned aside for a couple of days to visit it.

The Guild of Handicraft originated in an educational effort in East London. It began with classes for the study of design and the reading of Ruskin, carried on by the Guild's present head, Mr. C. R. Ashbee, at Toynbee Hall, the University settlement in East London. This was in the years 1886 and 1887. Reading led to designing, and designing to its application in practice, all in a small way at first. From this gradually grew a school in connection with a workshop, with the men in the workshop teachers in the school and the pupils in the school becoming gradually drafted into the workshop. When the Guild of three members had a school of fifty members, the indefatigable English benevolent subscribers stepped in—and here the story ends as an example of anything that would be possible in Canada. Funds were provided to carry the school through two trial years, on the top floor of a warehouse which became the school and workshop combined.

The school continued for nine years before it was extinguished by the State-aided competition of the London County Council Technical Schools. In the meantime it had not only had 700 pupils pass through its hands but had strengthened the Guild by the addition of a dozen or so of members, and their work was in demand. Beginning with wood and sheet metal work, they had added other works; they established themselves at Essex House, an old house in the East End, and became an established company of co-operative, autonomous workmen. Organization was in the hands of a committee; the committee elected a manager, who had a free hand in workshop discipline, but the individual guildsman had a right to lay his case before the committee. Such a thing as a real labor dispute is said to have never happened, and the value of the committee as a means of education, in the way of a sense of responsibility, steady and good work—in fact in the cultivation of a corporate conscience—is said to have been immense. The bonus at the end of the year is said to far outweigh, in the added sense of responsibility it gives, its actual cash value: Mr. Ashbee says "we have never found that the actual bonus made much difference; it is always the theoretical bonus that does the work."

Wages are paid on the basis of the Trade Union rate, wherever there is one, and the principle of inequality in human values is added. If, as sometimes happens, the Trade Union rate, in any individual case, is found to be in excess of the man's market value, the matter is settled by the manager and the Guild Committee in consultation.

It only remains, to complete the history of the Guild, to say that they are now a limited liability company, retaining as far as possible the good points of their original constitution. The workshop committee is still there, and the right of appeal from it to the manager; the committee does not, however, now elect the manager, which is done by the board of directors, but it sends a labor director to the board that does so.

A year and a half ago the Guild, finding itself enlarging to the point when expansion was inevitable, and as London is not an easy place to expand in, made what to an onlooker seems its happiest move, in establishing itself in the country. Having found in Campden, in Gloucestershire, a decayed town, with houses to be got for the workmen, it moved there about a year and a half ago.

High Street, Campden.

Campden, at the centre of the Cotswold wool growing district, was a great wool weaving town in the

A House in Campden.

fifteenth century and later. The old buildings remain—a fine church, some gothic houses, and some of

Renaissance periods ; all of stone. Mr. Ashbee himself possesses a house which contained the old wool merchants' hall, and he thus has a sitting room with a black timbered roof. The Guild workshop is an old stone silk mill in a garden—mill and residence one building, as was the happy way in those days. They have built a machine house with a gas engine and dynamos, for electric lighting and what machinery they use for preparing their wood ; the smithy is also out of doors ; for the rest the three floors of the woolen mill suffice for their several works which comprise, besides the blacksmithing : joinery, wood carving, metal work in silver and brass, jewel making, enamel working, printing and bookbinding. The clink of hammer and

The Guild Workshops, Campden.

metal, which one hears in approaching, strikes an ear, which is accustomed to the sound of machinery in such a building, with a sort of quaintness, analogous to the small scale of old buildings beside the new. Inside there is also a noticeable difference. Instead of a number of mechanics doing the same thing over and over again, and that only a step on the way to something they never know what, every man is here doing a piece of work which is usually his own from beginning to end; if not, it is only, as in the case of the carver, that his work finds its application in work that is done by other hands, and he is at any rate in touch with the work to which it is applied. This is a happy condition and it is no affectation to say that this workshop affects one's spirits pleasantly, whereas a machine shop suggests nothing but working between whistles; a terrible treadmill to which men have doomed themselves, as a consequence of mating. Here the Guild of Handicraft decidedly scores. The cant phrase, that art is the "expression of the workman's joy in his work," has here a chance of exemplification; a man may be interested in his work as well as in his wife. By so much more also that the work is done in a garden, and the air is fresh.

As to the work:—the blacksmithing is of course exactly what blacksmithing should be; a set of Guild fire irons (which, by the way, showed no loving marks of the hammer, but had a sort of lovingness in the soft section of the twist and in a certain whitey blackness of color) would be a pleasure to see—and to use. The smiths are also making electric fixtures which promise to be elegant, though iron. The snakey tendrils of the "pine apple pattern" come in well here. The trail of this serpent is over the work of the Guild. They have also come under the influence of Burne Jones' sinuous female with the high navel. In fact there is a school mark upon their work that seems to be conscious, and intended to suit a market that asks for the kind of thing. In their silver vessels—all of which are beaten out of the sheet metal—the hammer marks remain, because they say people like them so. Their silver work is certainly fine and is more substantial than spun silver. The hammer marks are very slight; not made for effect, but merely left, when the form is perfected, without further work; and the result is a sort of richness of surface; nevertheless, as these marks could be removed by further hammering, the dignity of a silver chalice seems to require that they should be removed. There is no particular virtue in the marks of the workman's hand, except as a trademark of the school that does handwork in an age when machine work is the rule.

Of the same kind is the square edged joinery of this school, which, I confess, bores me. If our rude forefathers did not know enough to mould, we do. There is something tiresome about this inability to adopt the method of good old work without adopting its manner too.

There is the same snare evident in the work of the hand printers. William Morris was not really a reformer in this respect. The Kelmscott Press was only an expression of discontent with the present; expressed by reverting to the past. But that sort of past is past. There is a clear field yet for any one who has been infected with the discontent and would allay it by creating a type with the beauty of usefulness. It is not necessary to create; the earliest printing, earlier than the period Morris preferred, has all the qualities of design combined with perfect legibility. Some of the publications of the Guild of Handicraft are printed in this type, making a perfect book. It is to be hoped that the Guild will be content to shine by this simple excellence. But the market for fine books is the market of the connoisseur and collector, perverted beings who from seeking the peculiarity of goodness have come to seek peculiarity as in itself goodness. The hand printer therefore finds it wise to make sure of his market by designing a special type which will mark the work of his own press; but to design a type that will have special peculiarities, and yet be as simple as the best type—which is the simplest—is a feat which will task even such an accomplished designer as Mr. Ashbee.

The Guild seems to have secured a field to itself in jewelry of modern design. There is a staff of men constantly employed supplying the Guild shop in Bond street, where the jewelry which is displayed makes a very attractive window.

They do also some good enamelling—a seductive looking work as applied to decorative landscape. It is simply glass dust floated on metal and fused in a furnace. Here is the principal difficulty, as the colour, without which the work is nothing, depends upon judgment as to the length of exposure in the furnace.

The great satisfaction in working in the Guild workshop, must after all be that designing and execution are, if not always by the same hand, at any rate in such close contact and communication, and standing upon such equal ground, that the designer is really in touch with his material, and this makes designing a pleasure because it makes good design possible.

W. A. Langton.

BRIDGE FOR THE CANADIAN NIAGARA POWER COMPANY.

By Orrin E. Dunlap.

A bridge that is being built by the Queenston Quarry Company for the Canadian Niagara Power Company has several interesting features. The site of the bridge is in Queen Victoria Niagara Falls Free Park, and it is to span the canal inlet leading to the forebay in front of the power station of the Canadian Niagara Power Company. When completed it will be one of the links in a beautiful driveway along the upper Niagara

New Bridge for Canadian Niagara Power Company.

River on the Canadian side, a locality that is just at present undergoing numerous changes as a result of the extensive power development now taking place there. These changes call for many new features, and this bridge is one of them.

The bridge is to be a concrete-steel structure with stone facing, and in general appearance will resemble somewhat the new bridge erected some months ago between the mainland and Goat Island on the New York side of the river. The length of the bridge to end of posts will be 298 feet. There will be five spans, each of 50 feet, and they will have rises of five feet. The piers will be eight feet wide on the face of the bridge and 66 feet 3¾ inches long to outside of cutwaters. The piers are set on bedrock, necessitating four or five feet of excavation. The stone used in the bridge is from Queenston, Ont. The piers below the springing line are pointed. The belts, washes and the coping are all of fine dressed work. Steel ribs spaced three-foot centers will be imbedded in the concrete of the arches. Portland cement is being used exclusively on the work.

The width of the bridge is to be 55 feet over copings, except at the piers, where there is a projection of about a foot, making the width of the bridge at the widest part about 57 feet. Inside of the copings the width is 52 feet, and of this 26 feet is to be devoted to double tracks of the Niagara Falls Park & River Railway, an electric line that skirts the river on the Canadian side, 20 feet to the driveway, and six feet on one side to a granolithic walk. The roadway is likely to be of porous gravel or cinders finished with macadam. The grade of the roadway will be practically level, the gutters being graded from the center of each arch to the piers, catch-basins being placed over each pier. Drainage is provided to be carried off in cast iron pipes that will discharge at about the springing line of the arch. It may be pointed out that the arches were made of such small rise in order to avoid raising the railway tracks, which will be on a fill approaching the bridge. The abutments of the structure are built of concrete in which large stones are imbedded. A conduit having four compartments has been built in the sidewalk for carrying electric wires for lighting the bridge, a pipe being inserted in each of the main posts. The specifications call for a loading of 5,000 lbs. per lineal foot on one track of the railway, and 100 lbs. per square foot on the driveway.

The arches and backing of the spandrel walls and the piers above springing line, are to be built of Portland cement concrete, the proportions of which are to be one part cement, two parts sand and four parts broken stone. In the piers below the springing line the proportions of the concrete are to be one part cement, three parts sand and six parts broken stone. In the construction of the bridge the contractor is required to trowel two inches of mortar onto the lagging in order to give a smooth surface on the concrete of the soffit of the arch. In building, the contractor is required to start the concrete simultaneously from the ends of the arch and lay it in longitudinal sections. While being built, timber forms hold the sections in place. The tops of the arches and backs of the spandrel walls are to be given two coats of pure Portland cement grout applied with brushes and then covered with two thicknesses of felt. This is in order that the arches may be made waterproof so that the dampness will not come through and stain the masonry.

Before the construction of the bridge a coffer-dam was built between the site and the waters of the river. The water that will pass beneath the bridge will flow to the turbines in the wheel-pit of the Canadian Niagara Power Company. High water will be 1.37 ft. above the springing line of the arch, which will be a depth of 17 9-10 ft. of water in the inlet canal. Low water will be 3.93 ft. below the springing line of the arch, or a depth of 12 6-10 ft. of water in the canal, while the mean stage of water will be 1.83 ft. below the springing line, or a depth of 14 7-10 ft. in the canal.

This beautiful bridge was designed by William A.

New Bridge for Canadian Niagara Power Company.

Brackenridge, one of the consulting engineers of the Canadian Niagara Power Company, and the structure is being built under the direction of Cecil B. Smith, resident engineer of the Canadian Niagara Power Company. It is without doubt to be one of the most beautiful bridges on the Canadian side at Niagara, and will be a material factor in adding to the new beauty of Victoria Park. Its magnificent lines and fine appearance will go well toward showing that even though industry has invaded the Canadian pleasure ground at Niagara, it is the intention of the park commissioners, and also of the Canadian Niagara Power Company, so far as it is concerned, to do nothing that will mar the natural beauty of the surroundings of the falls.

DETAILS OF MODERN HOSPITAL DESIGN.*

By A. Saxon Snell, F.R.I.B.A.

Under the title of "Details of a Hospital Ward," Mr. Snell spoke of some old principles of ward construction which ought not to be forgotten There is a tendency to consult new ideas at the cost of neglecting certain important sanitary principles. The author refers to several instances of new wards constructed upon the latest principles which have proved unsuccessful. As he says: "The old wards were known to be dangerously unclean, and special precautions were therefore taken to counteract their condition. The new wards were so very bright and clean that anything but perfunctory cleaning was scarcely thought necessary. In the old wards (which were dangerously unclean) the windows were kept open, and the very walls, innocent of plaster, were porous enough to be an assistance to ventilation. In their view it appeared that the provision of air inlets was thought to obviate the necessity of opening the windows." Another example of the neglect of well-worn principles is given. "The drainage of a certain building was relaid upon modern principles with manholes at every branch and change of direction. The old drains were always flushed periodically, and thus kept fairly clean. The new drains were supposed to act for ever without such assistance." The author says, five years after they were laid he made an examination of the system, "and was compelled to use a crowbar to open the covers of the manholes, which had never been touched since the drains were first laid." These are instances of the adoption of new methods of inspection which are never properly utilized. In another case the inlet ventilators of a ward were expensively constructed with glazed pipes. On visiting the hospital a year afterwards he found those flues black with dirt. They were never cleaned. Everyone knows it is an accepted principle of ward construction that all angles and corners should be rounded, so as to avoid all sharp angles and deep-cut mouldings where dust and dirt can lodge, and yet this principle is often subverted by the adoption of methods of flooring which harbor disease germs. The insistance of floors of smooth and impervious materials free from holes or crevices is one that cannot be exaggerated. Therefore, the author says plain-jointed soft wood floors are objectionable, as such wood shrinks, and thus leave joints for the secretion of dust and dirt, and are, moreover, absorbent. Speaking of hard wood floors, Mr. Snell has been in the habit of adopting kiln-dried maple in narrow widths, which is an "exceedingly hard and unwearable floor, its light color showing up dust more readily than dark woods." Oak and teak are commonly used, and the author says the terrazzo floors are advocated on account of their impermeability, though this is questionable, he thinks, when the high polish is worn off the cement. Asphalte is also useful, but its dark color is against it. As for finishing wooden floors beeswax and turpentine are recommended. The author speaks also of the importance of well rounding the angle between floor and skirting, a radius of 2½in. to 3in. being used; but Mr. Snell thinks 1¼in. radius enough, and this hollow or rounding must be formed of the same material as the floor. Sometimes hollow bricks are used for the hollowing, but the joints are numerous. On the question of wall surfaces the author does not discuss the advantages of either the porous or impermeable wall. Hygienically, we should prefer for hospital walls the cavity principle of construction, with materials sufficiently permeable to allow a degree of transpiration; but modern hospital practice has adopted the impervious walls, and the object aimed at is to make the interior wall surfaces as smooth and hard as possible, so as not to retain dust, and to be capable of easy cleaning. The germ theory is accountable for this view as well as for other modern ideas of construction, such as the rounded corners and angles. The hospital ward is often lined with tiles which make an impervious and clean surface; but practically the numerous joints are against it. A more perfect and smooth surface may be insured by a trowelled cement surface painted with enamel paint. Mr. Snell says: "It is scarcely possible to obtain a more generally smooth surface than trowelled cement—Keene's or Sirapite. These can be brought to a polished surface. It is difficult, if not impossible, however, to obtain a really even color. Although enamel paint can be used with decorative effect, pictures would still be required to decorate the walls, and the ordinary framed picture is a veritable dust trap. Therein tiled surfaces have the advantage of painted walls, as they can be decorated with permanent pictures painted on the surface. . . It would be possible to cover permanent wall paintings with glass let in flush with the wall surface, and I am not sure that this has not been done." There is an important suggestion here. We believe that for ordinary wards, painted tiled pictures of a quiet character and tone could be one of the best substitutes; a better would be panels high up or introduced in a deep frieze painted in distemper. We believe pictures can be fixed to the cement surface, and then covered as suggested by glass or enamelled, so as not to harbor dust, and be washable. A bare blank wall surface, even if colored a nice grey or in quiet tones of green, is monotonous if not relieved by pictures or prints, which appear to be necessary for the eyes of patients of an artistic temperament. The question is one that may well be considered by hygienists and architects engaged in hospital building. Ceilings are suggested to be best painted and non-porous; there are several kinds of paints in the market that may be used; and other appliances, like thin enamelled metal that can be bent easily, have been used. Touching the important question of windows, little definite information is given. The ordinary sash window, with a hopper and spandrel sides to prevent down-draught, is perhaps the simplest mode, and the author thinks that casement windows with solid frames are not open to the objection of angles, crevices, etc., involved in the sash window. At Willesden Parish Infirmary the author has used casement windows brought down to within 12 in. of the floor, and with hopper next the ceiling. The casements open inwards, and form a protection for the bed, and by opening them the wards can be flooded with air. At the Charing-Cross Hospital Mr. Snell is adopting the "Middlesex" windows, which include five sashes of equal size in the height, all of which, excepting the lowest, are hung on centres and controlled by one rod or lever. The sashes close one upon another, and there are no transoms. The lowest sash is hung on the bottom rail. The advantage of this form of window is that it can be opened to a larger extent than the ordinary sash window. All except the controlling lever is fixed on the outside of window, and if the glass can be fixed flush with the inner surface of sashes, it is desirable. For doors, hardwood, of course, is adopted, oiled or polished. Enamel paint is also a good substitute. Architects engaged in this class of building are naturally looking for doors without panels, which give a lodgment for dust and dirt. The flush panel doors are a step in the right direction, but the joints open and become crevices for dust. The author then refers to Canadian doors made up of small sections of solid soft wood, very closely fitted together and sheathed with hard wood, dovetailed on the whole, and pressed by hydraulic machinery. A flush-panelled soft-wood door, veneered with thin oak, seems to be all that is desirable, or a thin metal-cased door. In the fittings and furniture of wards the observance of the principles of smoothness, freedom from crevices, and projecting parts is quite as important. The author mentions some improvements in bedside lockers. The tops are now made of glass or marmorite, which is a valuable substitute for glass, and there are no unnecessary joints or crevices, and the whole can be cleaned. As for cupboards, they are certainly objectionable in wards, as they foster concealment of various things. A closed cupboard is used for holding surgical and medical appliances, medicines, &c.; but these should be placed, we certainly agree, not against the wall but in the centre of ward, and the cupboard should be made of hard wood framed and glazed all round, and have glass shelves. Heavy tables and chairs, so charming to the artistic instinct, are shunned by the hospital expert. Stoves are numerous, those made of iron plates and grills and moulded are not recommended; those built up with firebrick and tiles are preferred, as they are cleaner and better radiators. As to the important questions of heating and ventilation, nothing is suggested except that all pipes and fittings should be arranged so as to be easily kept clean; that controlling valves, etc., be kept out of ward; and that all flues with movable gratings in floors or walls, should be made easy of access for disinfection and cleaning. Mr. Snell refers to the deceptive and objectionable character of many sinks and basins on the market designed for hospitals which are made with glazed surfaces and rounded angles on the top and sides, but are death-traps underneath, full of pockets never likely to be cleaned.

*Abstract of Paper read before the British Sanitary Institute Congress, Bradford, England.

FIRE RETARDING WINDOWS.

The introduction to the report of the British Fire Prevention Committee on fire tests with prism glass reads as follows: "We have for a considerable time been applying various forms of 'fire resisting' construction, and various materials for the separation of fire risks, but we have somehow neglected the very necessary precaution of protecting such openings as have to admit light, and through which the spread of fire may involve an entire building.

"In the case of houses facing one another, in respect to buildings overlooking mutual areas, dormers overlooking adjoining roofs, and in many other instances where the separation of adjoining risks is all-important, protection of shutters and blinds had frequently been advocated, but the counter-argument has always been that shutters will not work in an emergency, or that their presence is entirely forgotten in the hour of need. As far as internal glass partitions, fanlights, glass panels to doors, etc., are concerned, nothing has practically been suggested, and hence there have been no arguments one way or the other on these points.

"It has been discovered by sheer accident, I believe, that, by adopting special methods of glazing glass, plain, plate or prismatic, will withstand a high temperature, and the application of water, and it is urged that by adopting such methods of glazing there will be no necessity for the shutter or the blind, inasmuch as the window or skylight will in itself afford considerable protection.

"The report which we now publish, and which gives particulars of the committee's official test with some glazing of this description, speaks for itself. The glass in this case was prismatic glass, but similar investigations will yet be held with plain glass and with plate glass, where this method of glazing is adopted.

"With plain glass and plate glass light, will, of course, be introduced in the ordinary manner, but with the prisms, light can be reflected into special directions and the lightness of a room enhanced.

"It is indeed interesting to have to consider a form of glazing which, besides being fire-retardant, is intended to enhance the lightness of a room, and the executive fully appreciate the importance and significance of their tests with this method of construction, inasmuch as the facts obtained should materially influence the reduction of the fire risk of the metropolis in a direction that has not yet been tried."

In the report of the National Fire Protection Committee of America the last paragraph in regard to glass fire retardents reads as follows:

"Your committee would recommend that the investigation as to the fire-retarding qualities of electro-glazed windows, and especially of luxfer prisms in electro-glazed frames, be continued, as results of fire tests, so far as noted, would indicate that in good fireproof window frames, and possibly with glass units reduced in size, electro-glazed windows may be useful under certain conditions as fire retardants. A fire-retarding window which at the same time is useful for proper distribution of light would be of value in a great number of instances."

Mr. E. U. Crosby, in his report to the National Fire Protection Association on the subject of light wells and other vertical hazards, includes the following among his conclusions:

(a) There should be no light wells; the loss of illumination due to abandonment of the light well can be more than made up by proper use of luxfer prism glass in wall windows, helped out in especially deep or angular buildings by the modern artificial white lights.

(b) Where such a well is allowed to exist it should be cut off from connection with each story with prism glass partitions set in non combustible frames, permanently secured in position. First story to be shut off from wall by a similar horizontal partition at ceiling level.

The right place for a fire escape is not right in line with window fronts, but on a blind wall, with connecting approaches or bridges.—Fireproof.

Messrs. D. H. Burnam & Co., the well-known firm of architects of Chicago, are said to have employed a staff of ninety men and are only prevented from employing a greater number by lack of office accommodation.

A NOVEL SUGGESTION.

We have heard a great deal in recent years about the smoke nuisance, as relating to industrial works. Some cities, including Montreal, have passed by-laws providing for the compulsory use of smoke consumers, which, if of doubtful value to the citizens at large, have been a source of profit to inventors and manufacturers of devices intended to burn or otherwise get rid of the smoke which constitutes a nuisance and a detriment to health when emitted into the atmosphere via the factory chimney. It remains for an associate member of the British Institute of Civil Engineers, Mr. G. T. Beilby, in a recent paper, to direct public attention to a new phase of this subject, viz., smoke abatement as applied to houses. Mr. Beilby estimates that in Great Britain 36,000,000 tons of coal are consumed annually in about 8,000,000 inhabited houses, and calls attention to the fact which probably nobody would dispute, that the domestic grate is at the mercy of a larger and more varied selection of incompetent stokers than any other coal-consuming appliance. As the only feasible means for abating this phase of the smoke nuisance, this author suggests that a chimney tax might be so applied as to stimulate and bring about the widest and most radical improvement in domestic heating. His plan would be to tax every chimney which is sufficiently wide to vent the products from the burning of raw coal, and leave free all those which are too small to do this. "This would at once place a premium on the use of smokeless fuel, as gas and coke can be satisfactorily burnt with very narrow chimneys. The production of these forms of fuel would be enormously stimulated, and the devising of appliances for their combustion would be encouraged. The architect and the engineer would have a new and fruitful field for their ingenuity and skill, and their trained efforts would in a short time greatly advance our practical knowledge of the subject."

"At present," remarked Mr. Beilby, "the 9 in. chimney holds absolute sway, and a house built without its full complement of these chimneys is looked on as abnormal and outside of the ordinary practice of those who buy and sell or who lend money on house property. The builder, therefore, declines to build houses which are really adapted for smokeless firing by gas or coke, with the result that these fuels have never had a chance of showing at their best." It is estimated that a tax of one shilling per chimney would yield a revenue of £800,000. Mr. Beilby's suggestion is an ingenious one, but it may safely be predicted that no attempt is likely to be made to put his ideas into practice. In Canada the general use of bituminous coal and the most approved devices for cooking and heating reduces to a minimum the amount of smoke discharged into the atmosphere. Here the necessity for ample size flues in chimneys must be urged, the tendency of builders being to make the area of the chimney too small, with the object in some cases, no doubt, of saving a little material.

The death is announced in Switzerland of Mr. Geo. F. Shepley, the well known American architect. Mr. Shepley was born in St. Louis in 1860, and received his professional education in Boston, being a graduate of the Massachusetts Institute of Technology. He entered the office of H. H. Richardson and on the death of the latter continued the business in partnership with Mr. Coolidge and Mr. Rutan who has been for many years connected with the office. The firm gained a distinguished place among the leading architects of the United States and carried out many important works.

ANCIENT LIGHTS.

The Ancient Lights Bill, the result of the labours of a joint committee of the Royal Institute of British Architects and the Surveyors' Institution, has been introduced by Mr. Fletcher Moulton, K.C., Mr. Robson, Mr. H. D. Greene, and Mr. Herbert Robertson, and was read a first time in the House of Commons on June 22; but, unfortunately in the present congested state of business, says The Building News, so useful and practical a reform has no chance of becoming law. The measure has as its full title, "An Act for Amending the Law Relating to Easements of Light," and it consists of eight parts and some twenty-seven clauses. Part I. provides that its operation is to be restricted to England and Wales, and Part II. consists of half a dozen definitions. Part III. deals with the limitations of the amount of light of a dominant owner, and Part IV. provides for the obstruction of an accruing light easement by notice in place of the existing clumsy mode of physical obstruction. Part V. provides that no title by presumption shall be acquired to light passing over a tenement on the opposite side of a street. Part VI. makes elaborate provisions for certificated plans of buildings about to be taken down, which will be a great interest to "official surveyors," by which term are described district surveyors in London, and county or borough surveyors elsewhere. Part VII. regulates the the statement of claims arising out of rights to light, and is the most verbose of all, and Part IX. provides for the construction of a tribunal of appeal, consisting of nine members, to be appointed in equal proportions by the Secretary of State, the R.I.B.A. Council, and the Surveyors' Institution Council.

NOTES.

The fire-escape, as ordinary built, is the ladder of flame.—Fireproof.

"None of the best headwork in art, literature or science, is ever paid for."—Ruskin.

"All good architecture is the expression of national life and character."—Ruskin.

"They say every man is the architect of his own fortune."

"That may be so, but usually he can't get intelligent contractors to carry out his ideas."

There is said to be a good demand in South Africa for good draughtsmen and architects' assistants, but not for architects wishing to engage in practice. Of these there are said to be many men already on the spot who are familiar with all local conditions, having been in practice before the war, and who therefore have much advantage above outsiders.

In answer to a correspondent who asks "what would be a safe load on solid concrete columns (composed of broken brick and cement) 13 ft. high and of 14 in. average diameter?" the London Builders' Record gives the following: If composed of 1 part of good Portland cement, 4 of hard-burnt brick, and 1 of clean sand, a safe load would be 10 tons; though concrete columns of the size stated ought to sustain 40 tons before they failed.

There was recently unveiled in Paris by the Minister of Public Instruction, a marble monument to Charles Garnier, architect of the Grand Opera House in that city. The monument is placed in an outer angle of the Opera House, and is, as it were, a signature upon the building. Upon the pedestal is traced a plan of the Opera. This is surmounted by the bust of the great architect, flanked by figures in bronze symbolical of Fame and the Graphic Arts. Charles Garnier was the son of a blacksmith. He was born in Paris in 1825, and at an early age showed an aptitude for drawing. When a young and obscure architect, he easily won first place in the competition for designs for the Paris Opera House, which is his best monument.

THE SCIENTIFIC BASIS AND COMMERCIAL FEASIBILITY OF HEAT RADIATORS, USING AIR INSTEAD OF WATER OR STEAM.*

By George M. Aylsworth M.D., Collingwood, Canada.

In the past many have thought that air could be used in radiators instead of water for the distribution of heat, and about twenty years ago a U.S. patent was issued covering the point.

The scheme, however, proved a complete failure owing to the radiator being simply a square box many times the capacity of the conducting pipes. The current of air was so rapid that it passed through this box radiator in a straight line and an enormously large proportion of the air in the box was not changed in temperature at all. As a consequence the hot air parted with but a small percentage of its heat, while passing through this box form of radiator. The general appearance and construction of the radiator is shown in Figure 1. The scientific reasons for the adoption of its peculiar form and the use of thin sheet metal in its construction are as follows:

The conditions requiring to be met were a distributing agent that would make the circuit of the furnace and radiators many times while water was making a similar circuit once. At the same time, the rapidly moving air would absorb much less heat from the furnace, bulk for bulk, than the slower moving water.

The problem therefore was to evolve a radiator that would compel the air passing through it to part with all or nearly all of its heat to the air of a room without diminishing the rapidity of the travel of the confined air.

The problem has been solved by the adoption of four devices.

Fig. 1.

First, by increasing the distance the air has to travel within a short space.

This was accomplished by the up and down or to and fro course the air is compelled to take in passing through the radiator. The distance from the centre of the inflow pipe to the centre of the outflow pipe is 2 feet, while the air travels in the radiator four and a half times as far, or an average of 9 feet.

Second, by offering the least possible obstruction to the passage of the heat from the air within the radiator to the air outside the radiator, but within the room.

This was accomplished by using sheet metal as thin as is consistent with rigidity.

Third, by compelling the volume of air to spread out into thin sheets so that all of it while passing through a radiator, should be kept as nearly as possible in contact with the enclosing metal.

This is accomplished by having the conduit through each section of the radiator, 1 x 7 inches rectangular in form, instead of round or square. The method of piping consists in having the area of the conducting pipe equal to the areas of the conduit or conduits in the radiator or radiators served by it. Also in having the volume of air necessary to serve a radiator, whether it have one or more sections, conveyed to the radiator in a single round or square column.

It will be noted that this method causes the difference between the circumference of the supply pipe and the conduits in the radiator to increase with each section that is added to it. The conduit in a single section has nearly double the circumference of its round supply pipe, while the conduits in a four-section radiator have three and one-half times the circumference of its round supply pipe.

The conducting pipes of a single section are round 3-inch pipes having a circumference of 9 inches and an area of 7 square inches, while the conduit through the section has a circumference

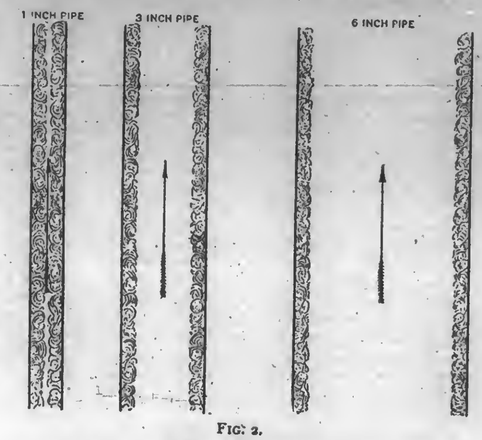

Fig. 2.

of 16 inches and an area of 7 square inches, or the same area as its supply pipe.

A four-section radiator is served by a 6-inch round conducting pipe, having a circumference of 18 inches and an area of 28 square inches, while the sum of the circumferences of the four conduits is 64 inches and the sum of their areas is 28 square inches, or the same as their 6-inch conducting pipes.

The extremely flat shape of the conduit through a radiator also prevents any part of the air it contains getting more than half an inch from the enclosing metal, while the centre of the air current through a 3-inch round pipe is 1½ inches away from the containing metal or three times the distance, and in a 6-inch round pipe, 3 inches or six times as far from the metal, and so with each change in the number of the sections in a radiator.

It is a well-known fact, which can be confirmed by observation

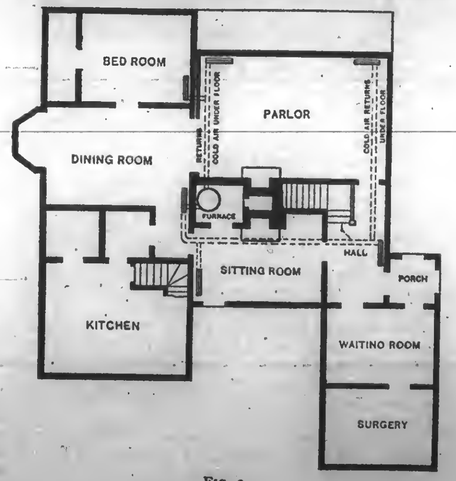

Fig. 3.

of any stream of water, that fluid in contact with the wall of a pipe, on account of the friction, takes on a revolving motion while passing through it, but the whole area of the current does not partake of this revolving motion unless the pipe is extremely small. The part of the area of the current that is unaffected by this motion increases in proportion to the whole area of the pipe, provided the rapidity of the current remains the same. (See cut).

*(Presented by request at the Summer Meeting of the American Society of Heating and Ventilating Engineers, Niagara Falls, N.Y., 1903.)

this fact in connection with the other facts—that air cannot possibly get more than one-half inch from the confining metal when passing through one of these radiators, and can get from three to six times that distance from the metal in the pipes conducting the air to them—suggests the vast importance of the flattened conduit through the radiator.

Fourth, by facilitating convection; by which method, in order to heat a room, all the air in it must be repeatedly brought into contact with the outside surface of the metal in the radiator.

This is accomplished by the flat form of the sections, and where there is more than one section in a radiator, placing them side by side with nothing to obstruct the flow of air between them from below upwards, as heat is imparted to it from the hot air within the sections. The results obtained in the following experiments by the use of these radiators will be a surprise to those who have not studied the subject and they were a cause for astonishment to myself, their originator.

In February, 1902, I fitted up a house that was in process of erection with a discarded wood furnace and rough hand-made radiators. The house was isolated and consisted of a cellar, ground floor, first floor and attic, and contained on the ground floor and first floor, 18,000 cubic feet of space; the cellar had a foot of ice on its floor which was chopped away from the immediate neighborhood of the furnace. The house is now brick-clad, but at that time was neither lathed, plastered nor bricked, and had many openings, large and small, through the outside walls from the cellar to the attic as well as through the roof. Ten radiators were placed in position, nine on the ground and first

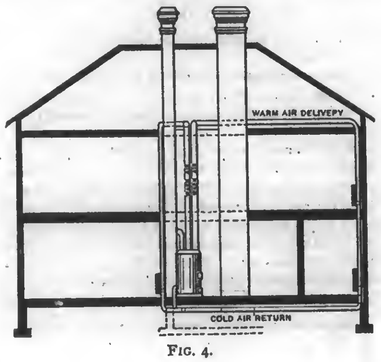

FIG. 4.

floor and one in the attic. A number accepted my invitation to visit the house on the afternoons of the 12th and 13th of the month. On the 12th, the outside temperature was 22 degrees Fahrenheit. On the 13th it was 12 degrees Fahrenheit, with moderate wind from the northwest. On each day all the radiators became warm within forty-five minutes after the fire was lighted. Two weeks later many of the openings had been covered with building paper preparatory to bricking the walls, the attic and cellar had been roughly shut off from the two floors, the house had been lathed with wet and frozen lath but not plastered, the temperature was 18 degrees Fahrenheit, with moderate west wind. The ground floor was brought to 63 degrees Fahrenheit within two hours after the fire was lighted. These results are phenomenal when we remember the wet lath and the enormous difficulty of heating a building when the plaster is wet, as pointed out by Mr. John Gormly at meeting last winter, in a paper entitled, "A time limit and dry walls necessary in testing a heating plant." The radiator in the attic was 20 feet horizontally and 20 feet perpendicularly distant from the furnace; it was the last of five on its main—two others having been supplied from the same pipe on each of the lower floors. The air entered this radiator at a temperature of 213 degrees Fahrenheit, and left it at 122 degrees Fahrenheit. Some of the heating experts present at this test believed, or at least said, while admitting the results, that the system would not stand a practical test of the many turns in the piping needed to place radiators at the points needed or preferred by house owners, nor would it succeed with the slower fire, as from anthracite coal.

To meet these objections, and having in the mean time had the radiators made in a presentable form, I fitted up my own house with them in 1903.

The house was an old-fashioned frame of two stories, the part served with radiators containing 17,000 cubic feet divided into ten rooms and two halls. There being no basement nor cellar, the furnace was set upon the ground floor and burned anthracite coal. It had never been repaired nor had its location been changed, although it had been in use for thirteen seasons. The ten radiators installed were supplied from three main pipes, two

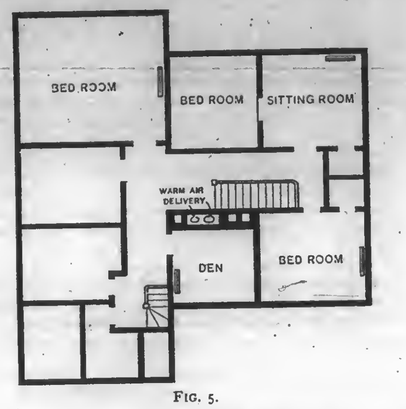

FIG. 5.

of these pipes conveyed the air through the attic before it reached any of the seven radiators; they served the ground and first floors; it was an overhead system, which it is hoped the accompanying plans will make clear.

The tinsmiths finished their work and a fire was lighted at 2 p.m. on the 19th of February. The next morning at 8 o'clock the temperature outdoors was 6 degrees Fahrenheit, and in the house it varied from 44 degrees to 60 degrees. The house was never as cold again, and after the first few days the system was better balanced and the variation within the house seldom exceeded 10 degrees, and only once did it reach 16 degrees, when the temperature outdoors was about 11 degrees, with a gale blowing from the northwest, the temperature within varied from 54 degrees to 70 degrees.

In passing from the furnace to two of the radiators, the hot air travels a distance of 62 and 71 feet, passing through the attic to

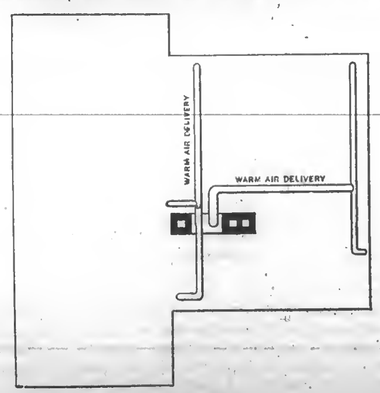

FIG. 6.

do so. In making the circuit from the furnace to these two radiators and back to the furnace, the air travels 107 feet and makes 13 turns, exclusive of the radiators, which if counted would make the air travel 116 feet with 21 turns, showing conclusively that turns in the piping have little or no effect upon the flow of air when it is confined and used in this way, and demonstrating how easily any probable conditions in any medium-sized building can be met with this system.

The foregoing results are much better than could be obtained with this furnace under the old system, for before the installation

of the radiators it had been found necessary, in order to get the same comfort, to supplement the furnace with two stoves and a large drum on the first floor. The latter utilized the heat from the smoke pipe of the furnace and it and the two stoves were done away with after the radiators were put in. Over and above this a very large percentage of the heat generated by the furnace is wasted, while the hot air is passing through the pipes in the attic before reaching the radiators. For the large amount of piping in the attic kept it at a higher temperature, notwithstanding attempts at insulation, than either of the lower floors, which of course was not the case before the radiators were used.

As to the consumption of fuel, it is impossible to be exact in connection with these experiments, but the quantity consumed during the two and one-half months the radiators were used would indicate that the present arrangement will not require more than the old one has done.

One of the reasons for uncertainty in estimating the consumption of fuel, in addition to the removal of the two stoves and heating drum aforementioned, is its rapid diminution, as the best method of running the furnace under the changed conditions was learned—for instance, two tons of coal were consumed in the first 18 days, a third ton in 11 days, or (omitting fractions) a ton every 11 days. A fourth ton was burned in 23 days, and a fifth in 18 days, or a ton every 20 days. That is an average per day of twice as much burned during the first 29 days than was burned

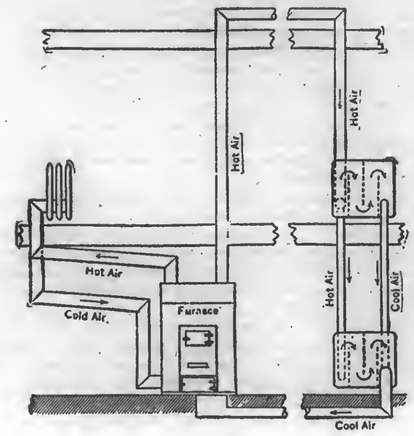

FIG. 7.

during the last 41 days, though the average was within a degree of being the same in each of the two periods with increased comfort during the latter. The rate at which the coal was consumed during the 41 days is almost identical with the rate of consumption in the past when registers were used.

The diameter of the fire pot in this instance is 18 inches, because the builders of the furnace claimed that that size pot was plenty large enough to heat 18,000 cubic feet. But this, as was not unusual in those days, was an overestimate, and at the present time it is unusual to find a reliable hot air furnace-maker making such a claim even when the familiar instructions—"Locate the furnace so that all hot air pipes shall be as short as possible" and "Place registers as close as possible to the furnace" are closely followed.

In this test of hot air radiators these rules have been purposely violated, and the departure from them is so wide that it is believed that 50 per cent. of the heat from the furnace is lost in transmission to and through the attic.

It is not anticipated that any one in his senses will adopt such an overhead system except under compulsion, neither can it be expected that the results under the conditions of this test should be ideal, yet they are the basis of the confidence felt that the proper installation of these hot air radiators will demonstrate beyond all question, during the coming winter, a decided economy in the consumption of fuel through their use.

DISCUSSION.

Secretary Mackay: Before starting a discussion I move a vote of thanks to Dr. Aylsworth for his courtesy in preparing this paper and presenting it to our Society. The motion was carried.

Prof. Kent: I notice that the rate of coal consumption is said to be the same as when registers were used, and would like to ask what is the advantage of this system?

Dr. Aylesworth: A large proportion of the heat was wasted—I estimate 50 per cent.—by passing through the attic, so that there was really more heat produced from the fuel.

Another advantage is that the air does not pass over the excessively hot surfaces of the furnace and then into the rooms, which is one of the points raised by steam and hot water advocates as an objection to the use of furnaces.

Mr. Switzer: Had you any supply of outside air?

Dr. Aylesworth: None whatever. My house has a large ventilating shaft, but there is no ventilation in connection with this air that passed through the radiators. The shaft passes between the two chimneys, up through the roof, forming a continual exhaust from the rooms; there are also two fireplaces on the ground floor.

Prof. Kent: How serious is the objection to having the air pass over the furnace in the usual way and be discharged into rooms?

Mr. Cobey: There is more or less objection to burning out certain elements of the air before we breathe it.

President Crane: The temperature given for the air passing into the radiator is 213 degrees, and that at the exit 123 degrees—a little hotter at the entrance and cooler at the exit than in a well balanced hot water apparatus, which is not commonly more than about 180 at the flow, with a diminution of about 15 degrees at the return.

Prof. Kent: This strikes me as a very well designed system for the results sought to be accomplished. Reducing the temperature from 213 to 123 shows an excellent design of the radiator, and the piping system must also be very well designed in order to avoid short-circuiting the air. In larger houses, with more branch pipes, I should expect more difficulty in circulating the air uniformly.

I do not see that pure air is hurt by passing over surfaces at 300 or 400 degrees. If it contains bacteria you may cook them and have a bad smell, but I think that is unimportant in practice.

A disadvantage of this system is that it does not ventilate as do other furnace systems, which is a strong argument in their favor.

This system would circulate just the same if the radiators were left out. The air would be discharged into the room, be breathed and returned to the furnace to be reheated. A disadvantage would be the possible leaks in the furnace.

Mr. Feldman: Dust contained in the air passed over a furnace is sometimes burned in cold weather, and can be smelled.

Mr. Roys: In an ordinary furnace-heated house the wind forces the heat to the other side of the house. In this case the circulation is not affected by the wind, which is a very great advantage.

Mr. Allen: In Fig. 4 the two circuits of pipe are shown as very unequal in length. I would ask if they are of the same size?

Dr. Aylesworth: No; the size of a pipe is governed by the amount of radiating surface it supplies.

Mr. Oldacre: How is the radiating surface proportioned to the contents and exposure of the rooms?

Dr. Aylesworth: The same as with steam or water.

Mr. Switzer: What is your source of air supply? If some of it escapes and the supply is insufficient to carry away the heat from the furnace, fuel would be wasted.

Moreover, it would shorten the life of the furnace to reduce the quantity of heat taken away from its surfaces.

Dr. Aylesworth: The system is not absolutely air tight any more than an ordinary furnace is. In practice, the furnace was used for two or three months and there was no perceptible loss of power, either by diminution of the volume of air or deterioration of its quality.

Mr. Oldacre: If in a furnace heated house one side is colder than the other the work is not properly done.

Secretary Mackay: I do not agree with Mr. Oldacre. I think that in 90 out of 100 cases the furnaces on the cold side of a building act as a cold air supply. I take it that the doctor heats his house more satisfactorily with the present system than he was able to before with the same furnace.

Mr. Chew: An ordinary furnace is to some extent preserved by the constant flow of cold air over its surfaces. In this case the

surfaces are exposed to what is comparatively a hot blast. The question is, how long will the furnace stand such treatment?

Mr. Cobey: I do not think a fire pot is more likely to be destroyed by passing 120 degree air over it than by air at zero, which is likely to disturb the iron by unequal contraction.

Mr. Chew: Moreover, to raise air from zero to 200 degrees the fire pot would have to be white hot, which would not be necessary if the return air is at 100.

Mr. Oldacre: I have never observed any deteriorating effect from cold air—even 10 below zero. The highest temperature of air discharged from a register, in very cold weather, was 190, which I consider too high, and that more air, at a lower temperature should be used—not above 150. The larger the volume of air the more nearly it approaches the quality of outside air.

Mr. Roys: I think Mr. Oldacre is speaking of an ideal system, while the Doctor is speaking of common practice. In my experience I find the air coming from registers as high as 400 degrees, and only getting down to 150 in mild weather.

Mr. Oldacre: Would not the casing of this furnace be so hot as to lose much heat in the cellar? When air is taken from outside the casing is so cool that you can put your hand on it. When I have found a hot casing it has indicated poor circulation, or some other trouble.

Mr. Roys: As a furnace is commonly installed it would often be impossible to even touch your hand to the top of the casing. I believe the fire underwriters say there are more fires caused by hot flues than any other cause.

Mr. Oldacre: I would like to have pointed out to me a single case where a house was set on fire by a hot pipe—I do not mean the chimney.

Mr. Roys: Mr. Sims, of the board of underwriters, claims that there are hundreds of such cases.

Mr. Switzer: I know of such a case. The wall pipe was not protected in any way and the pipe was air bound, so that it did not circulate. It was in 10 below zero weather, with a 30 mile gale forcing the air into the lower rooms, which grew colder, and this pipe to the second storey got hot enough to ignite the wood work

One of the objects of this society is to educate men to put in furnaces as perfectly as those Mr. Oldacre describes, which it is entirely possible to do.

Secretary Mackay: Dr. Aylesworth does not mention any valves or dampers to shut off the heat from a radiator. What effect would it have on the furnace to shut off one room or more?

Mr. Cobey; The system is in a primitive state, and the controlling appliances can easily be added. I think we shall some time adopt the direct radiation with separate provision for ventilation. I do not think it desirable to introduce the heat and the air for breathing through the same duct as it often gives a bad odor.

Mr. Schaffer: Answering a question of Mr. Chew, I will say that a furnace supplied with air from inside will last longer than if supplied with air from outside.

Prof. Kent: I would ask the size of these radiators.

Dr. Aylesworth: My present idea is to limit the radiators to four sections, of about 14 square feet of surface to the section.

In regard to heating the cold side of the house with these radiators, the colder the exposure the more rapid the circulation in the exposed radiator.

In regard to dampers, the instructions to the manufacturer who shipped this radiator here, were that he should put the damper in place, in the inflow pipe of the radiator, at the bottom. The effect of closing a damper would be the same as closing the register on any furnace, or any steam or water radiator.

For special ventilation it is planned to place another pipe outside of the exhaust pipe of the radiator, and connect it with the outdoor air.

Prof. Kent: I would ask how the Doctor gets a loss of half the heat in the attic?

Dr. Aylesworth: The attic covers the whole building, has roof exposure, and was kept warmer than the rooms below; there was a good deal of piping in it—the pipe, which is 10 in. at the start, runs 34 feet.

Prof. Kent: How would you change that in another building?

Dr. Aylesworth: Put the horizontal pipe below the floor.

Mr. Chew: I notice in Fig. 7 two systems of piping are shown; that at the right going up through the attic and that at the left being a direct flow pipe along the cellar ceiling, with a pipe up to the radiator and coming directly back. I would ask the Doctor's preference.

Dr. Aylesworth: It is decidedly preferable to carry the pipes through the cellar.

Mr. Oldacre: What are the advantages of this system over hot water or steam?

Dr. Aylesworth: It is cheaper to install and the expense of repairs is slight.

NORTHWEST LETTER.

(Special Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

WINNIPEG, Sept. 9, 1903.

Although the building season here is not by any means closing in, yet all important work that is to be roofed before the hard frost comes is now well under way. The season has been a most satisfactory one from a builder's point of view and the amount of work that has been carried out is almost incredible compared with that done in former years. The great advance in prices both of material and labor this year would, it was expected, cause buildings to be cancelled to such an extent as to possibly retard the progress of the city, but contrary to expectation the quantity of work proceeded with has been so great that only by the united efforts of the contractors has it been successfully coped with.

Apart from the business blocks, warehouses, etc., the number of residences in course of construction is enormous, and although most of these are not of a very high order of architecture yet the relief they will give in this direction is most edifying. The better class of residences have been somewbat affected by the price of material and labor and in the way of intricate planning and elaborate finish and detail, they do not call forth much comment. The plans of most of these houses are carried out on the first principles of the square and the elevations have taken a correspondingly uninteresting position. To build with the least cost has been the ruling factor governing all this class of work. Several larger residences were contemplated early in the season but what was considered prohibitive prices caused the work to be postponed indefinitely.

The Steel Apartment Building, Portage Avenue, although not properly under the head of residences will ease the pressure to a considerable extent in the increasing demand for rooms. This is a six-storey building and on plan it is practically a square with a large central light well extending from the first floor to the roof. On each floor a gallery is carried around the well by which access is obtained to the different suites. The staircase and passenger elevator are taken up through the light well and connected directly with the several galleries. The single staircase appeals to one as rather a serious drawback to the satisfactory working of a building of this character, especially with the capacity this has of accomodating such a large number of people. A separate tradesmen's entrance and staircase would if arranged greatly facilitate matters and solve the problem of efficient service to the different floors. Each floor is divided into eight suites, each containing from three to five rooms with a bath room to every suite. A rather doubtful arrangement has, I think, been planned for the bath rooms and kitchens. These rooms are all lighted from the central light well, this light well itself being covered in with a skylight and rendered practically a closed area. In elevation the building is extremely simple; the material is buff pressed brick (Lac Du Bonnet) and Tyndall stone bands.

Apropos of residences, I am sending you for this issue of the CANADIAN ARCHITECT AND BUILDER a photograph of a summer house for Mr. R. Wilson. This house is beautifully situated on the bank of the Assiniboine river at St. James, about four miles west of the city. In plan it is rather interesting, and I enclose a rough line drawing of same. The front of the living room opens by means of glass doors, the full width and height of room, so that in warm weather this room becomes practically a large verandah. The kitchen arrangement is most satisfactory as it is really quite detached from the remainder of the house and all heat and odor emanating therefrom is kept absolutely clear of the living rooms.

In taking up the larger work the banks call for the most attention. The completion of the Bank of British North America has been somewhat hampered on account of the delay experienced in waiting for stone and progress for this reason has been much slower than was anticipated. The work will, however, be ready for the roof towards the end of the month.

The contract for the Union Bank's eleven story steel frame building has been awarded to the Fuller Construction Company, of New York. It is needless to give a dissertation on the status

of a company which has reached such unprecedented records both in the amount of building continually under its supervision and in the remarkably short space of time in numerous instances required for the erection of same. The company is commonly known as the pioneers of steel frame buildings and their name is synonymous with "sky-scraper." The receiving of this contract has caused a new departure in the business of the Fuller Construction Company as it opens up a field in Canadian work which up to now had not been entered upon. Although the granting of the contract for such a large work would perhaps have been more satisfactory if it could have been given to a Canadian firm, yet in the present instance it can hardly be looked upon with disfavor. The methods employed by such a company, who are habitually used to command material and labor in any proportions, will be most interesting to follow in this western country where the supply of material of all description is chronically infinitesimal. To push a work of this category in Winnipeg with anything like the marvelous rapidity with which it is consummated in the States would from our present mode of building be nothing short of a miracle, and the entry of such builders amongst us cannot help but accelerate the movement of material in all quarters, and the benefit accruing from such cannot fail to eventually benefit the community at large.

The undertaking of a building of this description by the Union Bank cannot but be an incentive for other institutions of like calibre to follow and we may in the near future anticipate a series of like structures to be erected.

The building of the Carnegie Public Library is at last under way. The commission for this work was finally awarded to Mr. S. Hooper, architect. The original competition, open to all architects in Winnipeg, was after much turmoil and many stormy and unprofitable meetings, cancelled by the City Council on the grounds that the tenders on the first three selected designs were above the stipulated cost, and the remainder of the designs (five) not meritorious enough (presumably) in their opinion to warrant them considering same for tender. A second competition was subsequently held when Mr. S. Hooper and Mr. F. S. Griffiths were invited (the remaining original competitors ignored) to again submit plans in competition. Mr. S. Hooper was the successful competitor in the duel. Messrs. Smith & Sharpe are the contractors for the work and they expect to have the building closed in before the severe frost arrives.

Augustine Presbyterian church, Fort Rouge, Mr. J. H. Russell, architect, is well under way. The cost of the work is roughly about $40,000. The building will be faced with Tyndal stone throughout.

The Land Titles large new building on Broadway is progressing, but sufficient work has not yet loomed up to judge of anything relating to design.

The vote on the City By-law asking for an additional $60,000 for the addition to the Winnipeg General Hospital resulted in rather a peculiar manner. The total vote polled was somewhere about 2,000, and out of this number less than 100 voted against. As the law governing a poll of this nature stipulates that ⅔ of the total number of names on the voter's list must be cast the measure was at first thought to be lost on these grounds. The matter has, however, been taken up by the City, and legislation is now being sought whereby the poll can be legalized, as the vote showed that it was only through apathy on the part of the citizens that the by-law was not carried through. The passing of this measure by the Government is now practically settled and work is being proceeded with accordingly.

Nothing definite has yet been decided upon by the Canadian Pacific Railway regarding the projected new Subway, Station Hotel, etc., although work may commence here at any date.

W. PERCY OVER.

THE CANADIAN BUILDING AT THE ST. LOUIS EXPOSITION.

The contract for the erection of Canada's Pavilion has been awarded to John J. Dunnavant & Co., the contract price being $28,000. The building will be 100 feet square, two stories, and surrounded by porticos. The architect is L. Fewings Taylor, of Ottawa, Canada.

The building must be completed by December 1. A permit for its erection has been issued, and Mr. Dunnavant says he will commence work at once.

The Canadian reservation is about half way between the Agricultural Building and the Forestry, Fish and Game Building. The handsome pavilion which is to be Commissioner-General Hutchinson's official home on the World's Fair Grounds next year and which will serve as a club house for Canadian visitors to the Exposition, will stand southwest of and close to the big floral clock on the northern slope of Agricultural Hill. The building will face the avenue which runs north and south in front of the Administration Building and extends to the Agricultural Building.

The National Fire-Proofing Company, of New York, have published a leather bound Catalogue containing many useful tables giving safe loads and illustrating methods of fire-proof construction. The price of the book is $3.00.

Attention is called to the advertisement in this number of the Canadian Casualty & Boiler Insurance Company, whose head office is in Toronto. The managing director of this company, Mr. A. G. C. Dinnick, is a gentleman of ability and large business experience. He has associated with him men having the high standard of technical knowledge requisite for the proper inspection and insurance of boilers, &c.

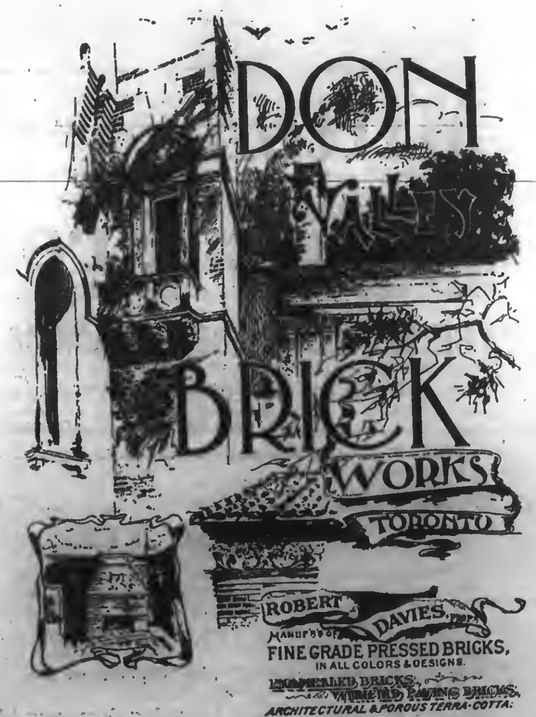
NOTES.

The price of bricks in Vancouver has recently been advanced by $2.00 per thousand, the price now being $11.00.

At the Dominion Fair and in fairs throughout the country the Dunlop exhibit of rubber mats, rubber tiling and rubber flooring, was a particularly interesting display for house owners and house builders. The company have introduced many new features both in designs and material. Their new catalogues are now out and are worth investigating.



A DEPARTURE IN HOT AIR HEATING.

Our readers will no doubt be interested in the paper printed in this issue by Dr. George M. Aylsworth, of Collingwood, describing a new method of heating, of which he is the inventor. In Dr. Aylsworth's system hot air is circulated through pipes and specially constructed radiators in the same manner as hot water is employed in hot water heating systems. The system is a distinct departure from the methods at present in use, and on that account alone is interesting. It remains to be seen whether in actual every day practice, it will fulfil the expectations of the inventor. In some rather severe tests which have already been made of the system by the inventor, it is said to have proved satisfactory. We would be pleased to publish the opinions of any of our readers with regard to this system.

WIRING METHODS AND MATERIAL.

We have previously had occasion to call attention to the crying need for improvement in the way in which electrical machinery and wiring is often installed, but the frequency with which cases of criminally careless work come to light, let alone those which at the best are but botchwork, would seem to indicate that the matter is in many cases being entirely lost sight of. As an example we would cite an installation which recently came under our notice in which a 2200 volt line was carried into the basement of a building, no lighter and no dryer than basements usually are, with ordinary weatherproof wire, run on knobs. At several points it had been necessary to insert connectors, parts of which extended to within two or three inches of each other and were not even taped over, notwithstanding that they were within easy reach of anybody passing, being but four or five feet from the floor. Further than this, ordinary lead composition fuse wire, bare, was in use. Compare the above with a proper equipment of rubber wire and enclosed fuses, the former run in conduit and the latter with their necessary connectors and mountings boxed in cabinets, and you will have some idea of its shortcomings. At another installation, a woollen mill, with its usual contents of highly inflammable material occupying all parts of the building, to say nothing of the lint and dust which invariably accompany such processes, there was found the old familiar open lead fuse, some in cutouts with porcelain covers and some without even this slight protection. This meant that the blowing of one of them was almost certain to ignite the pile of material immediately below it, with ultimate results which can easily be imagined. Proper enclosed fuses, installed in cabinets, would have cost but a trifle more and would have made a fire of electrical origin a remote possibility, instead of a large probability. Is it any wonder that when work such as found in the above instances is allowed to be put in, that the uninformed public, and for that matter, many who claim to be well posted, look askance at the proposal to introduce electric power. In the former of these cases the installation was a positive menace to life, and both offered every chance for a severe fire.

NOTES.

Under the direction of the Montreal Industrial Exhibition Association arrangements are being made to hold an important exhibition and fair in the city of Montreal in 1904.

An exhibit of Canadian building stone from the collection of the Geological Survey of Canada, was one of the interesting features of the recent Dominion Exhibition in Toronto.

The Allith Manufacturing Company have leased the building formerly occupied by Leitch & Turnbull at Hamilton, Ont., and will engage in the manufacture of track door hangers and other kinds of hardware.

With the aid of a ginpole, instead of derricks or travellers, for hoisting materials, Chas. T. Caldwell, of Columbus, Ind., is said to have made a record for rapid construction on the St. Louis Fair Grounds. Within fifty days he is said to have completed the Agricultural Building, 1800 feet long by 600 feet wide.

The most artistic and durable color effects on shingles are produced with Shingletint, which is a scientific combination of linseed oil, coloring matter, creosote, and the necessary drying agents.

Among the many shingle stains offered Shingletint is conspicuous not only for its superiority but because it can be called for by its distinctive name, thus offering the consumer protection against inferior goods offered for the same purpose.

When buying Shingle Stains it will be worth while to ignore the "just as good" argument and insist upon Shingletint.

BY THE WAY.

The theory that lightning never strikes twice in the same place has again been disproved. The new municipal buildings, Toronto, the tower of which was partially destroyed by lightning last year, was again struck last month. The damage was but slight, however, only one stone being displaced.

× × ×

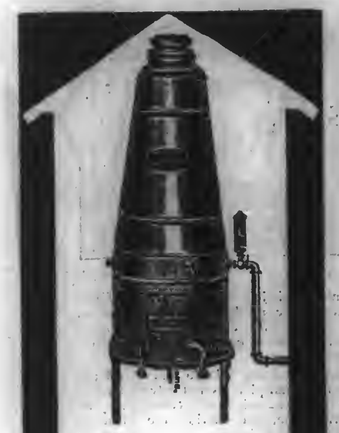
Notwithstanding loss of commissions as the result of building projects being blocked by recent strikes, some architects whose offices had for months been crowded with work, and who had consequently been compelled to work early and late were disposed to welcome the interruption as affording them opportunity for needed rest. However, a shorter period than three months would have sufficed for this purpose.

× × ×

Before the Court of Revision in Toronto the other day an appeal was made by the owners of two of the largest office buildings in the city for a reduction of assessment. One of the reasons urged in behalf of this appeal was that the revenue from these buildings netted the owners only two and one half per cent. on their investment. If this statement be accurate, it must tend to discourage investment in real estate of this character.

× × ×

Bow church, to the Rectory of which Mr. Hutton, the late librarian of the National Liberal Club, is being instituted, possesses what Darwinists would call a "survival," says the Westminster Gazette. This is the curious balcony beneath the clock, which represents the medieval tower from which the Court witnessed the tournaments in Cheapside. It was originally a wooden structure, which on one occasion collapsed, so that Queen Philippa and all her ladies "fell with great shame" on the heads of the assembled knights. Jerry building was discouraged in those brave days, and the careless carpenters were ordered to be executed. The royal balcony was last used by Queen Anne in the first year of her reign at a "pageant" devised by the "City Poet," Elkanah Settle.



Every house should be fitted with one of our instantaneous water heaters.

These heaters are practically indispensable as they provide hot water as wanted on an instant's notice, and are free from soot, smoke and smell.

They cost but a trifle to run and are so neat and compact that they add to the finished appearance of any house.

Carpenters' and Builders' Standard Library

BY FRED T. HODGSON

Each volume a veritable gold mine of up-to-date information for the architect, contractor, carpenter, mechanic and apprentice, or anyone who would work with wood. These volumes have been issued since September, 1902, and must not be mistaken for Mr. Hodgson's former works which were published some twenty years ago.

This series of Fred T. Hodgson's new works are to-day the approved and most helpful set of practical builders' "educators" published. They have been tried and found by architects, contractors, carpenters and builders to be efficient "aids" for advancement and thoroughly reliable for daily consultation as books of reference, covering as they do thousands of "self-help-points" necessary for all workers of wood.

The books are positively up-to date and we most heartily recommend them to everyone as the most valuable series of books for self-instruction published in the world on the subjects treated.

THIS OFFER WILL EXPIRE WHEN THE 5,000 SETS ARE SOLD. AFTER THAT, THE BOOKS CAN ONLY BE HAD AT THE RETAIL PRICES.

If you want a prospectus which gives the full contents of this valuable work write us for it. *Sent Free.* Send Post Office or Express Money Order to avoid delay. Your money will be cheerfully refunded if the books are not as represented. Address all orders to

A Commendable Work

The Canadian Club of Toronto is performing a valuable public service by marking historic spots in the city and vicinity. During the last five years the Club has placed bronze tablets bearing suitable inscriptions on a number of ancient buildings and on new buildings erected on the site of ancient structures which were the scene of no able occurrences in the early history of the city and province.

Wages and Working Hours in the Building Trades.

An interesting table is published in the September number of the Canadian Labour Gazette, showing the changes that have taken place in working hours and wages of mechanics in the building trades in Canada during the present year. In ten towns and cities the wages of bricklayers and masons were increased by $1.00 to $3.00 per week; in fifteen towns and cities the wages of carpenters were increased from 25 cents to $3.00 per week. In Montreal, plasterers obtained an increase of $1.36 per week, and in Toronto $2.20. Wages of plasterers' laborers also advanced by $2.20 per week. Painters, decorators and paperhangers in eight cities got increases ranging from 65 cents per week in Montreal to $2.78 in St. Catharines. The wages of plumbers and gas fitters in six cities show advances ranging from 50 cents per week in St. Catharines to $5.33 in New Westminster, B. C. Stonecutters were given increases ranging from $1.50 to $4.00 per week, and builders' laborers of 28 cents to $2.10 per week. Coupled with this general rise in wages there were in many instances reductions in the number of working hours.

The Eiffel Tower

The municipal authorities of Paris have in view the purpose of transforming the Champ de Mars into a park. This means that the portion of the site of the Exhibition of 1900 lying south of the Seine, must be cleared, and that seven years hence, when the concession for the Eiffel tower will expire, that great and novel structure will disappear, and with it the most conspicuous modern landmark of Paris. For boldness of conception, and as an example of original and artistic design, the Eiffel Tower deserves to rank, as it has done since its erection, among the wonders of the world, and the necessity for its removal will be generally regretted.

Wall Papers

Attention is being called by the technical press of Great Britain to the fact that the export trade in wall papers to Germany from Great Britain is diminishing. A few years ago British manufactured wall papers were in large demand in Germany and a

profitable trade was built up. While it is claimed that the British manufacturers have neglected to put on the market new and attractive patterns, the Germans have greatly improved their manufacturing facilities, and are not only supplying to a considerable extent the home market, but are exporting largely to other countries. Their exports have, it is said, increased by 83 per cent. during the last five years.

Dismissal of an Architect.

Under the provisions of the Tarnsey Act leading architects in private practice have for several years received commissions from the United States government to design and superintend the erection of important public buildings. Such commissions must be won in a limited competition. In this manner Mr. Henry Ives Cobb was appointed architect of the new government building in Chicago. He was recently dismissed from the position with the concurrence of the supervising architect of the Treasury. The reason given for his removal is that he proved himself seriously lacking in business qualifications. The contracts in connection with the Chicago building are said to be in a muddle. This incident proves conclusively that the architect of to-day who aspires to surpervise the construction of important buildings must himself possess a thorough knowledge of business methods, or must have business men as associates. It is to be hoped that the dissatisfaction and trouble experienced by the United States government in this case, may not result in the repeal of the excellent law under which a stimulus is given to architecture profitable alike to architects and the nation.

The Housing Problem.

For many years in London, New York and other large cities the question of the best means of providing accommodation suited to the requirements and within the means of laborers, artizans and persons with small incomes has received much attention. The time has now arrived when this problem also demands consideration in the larger Canadian cities. In Toronto, where at present all classes of houses for rental are at a premium, families who are only able to pay a rental of from $10 to $18 per month, find it impossible to secure accommodation within this price limit. It is claimed that land values within the city coupled with the advanced cost of building and building restrictions will not permit of a fair return to owners of moderate cost houses, cousequently few are being built. So long as present conditions obtain there would seem to be but two feasible methods of meeting the demand for accommodation of this class. One is to erect flats in central locations within the city, which is the plan adopted in New York. The other is to build suitable detached or semi-detached houses beyond the city limits and provide means of rapid transit to and fro. From the standpoint of comfort, health and morals, the last mentioned plan seems to possess great advantages.

It can scarcely be hoped that the problem will be met either in one way or the other on strictly business lines. It must be undertaken in a large way and to some extent in a philanthropic spirit. In other words, those who put their money into the enterprise must be satisfied with a moderate return on their investment and find the balance of their reward in the assurance that they have helped to smooth the pathway and elevate the standard of living of their less favored fellow citizens. It is to be hoped that men of wealth may be found actuated by these motives, to give money, time and thought to the solution of this important problem of the present and future.

The Cement Industry.

The failure of the Consolidated Lake Superior Company's enterprises at Sault Ste. Marie last month resulted from the want of exercise of sound judgment by the promoters and managers. This failure is not only a serious blow to the shareholders, many of whom are Canadians, to the thousands of employes, and the business interests of the Sault, but also to the advancement of the whole province. It should teach the necessity for caution to the promoters of other industrial enterprises, including cement manufacturing concerns, of which we are in danger of having a surplus. The days of large profits in cement manufacturing seem to have gone by, and investors will do well to acquaint themselves with the conditions and discount the statements of glib-tongued promoters and stock peddlers, before parting with their money.

It is rumored that some recent enterprises in this line have been to a large extent stock jobbing schemes. The promoters are said to have received for their services large blocks of stock which they converted into cash as speedily as possible, leaving to the legitimate shareholders the responsibility of making the enterprises pay, which, in the case of over capitalized concerns is proving a by no means easy task.

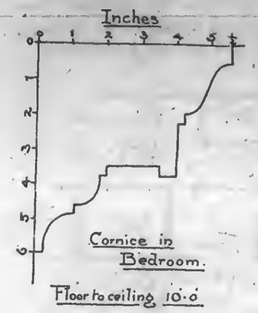
Some of the better class of technical journals in the United States are pointing to the experience of Germany as a warning against the investment of money in new cement manufacturing companies. Under the stimulus of a demand for cement for large public works manufac ories in that country rapidly increased until there were 261 of them, with a capacity of 29,000,000 barrels. Then the home demand dropped and the mills found themselves with a surplus stock of about 12,000,000 barrels.

The annual report of the Ontario Bureau of Mines lately to hand estimates the quantity of cement representing a year's consumption in the whole of Canada, at 1,100,000 barrels, and the possible consumption of 1903-4, taking into account the development of the country and the multiplying uses to which the material may be put, at 1,200,000 or 1,300,000 barrels. The yearly output of the factories as at present equipped, if all were working full time, is placed at 1,150,000 or 1,200,000 barrels, and when the improvements now in progress are made, it will rise to 1,700,000 barrels. The latter quantity is in excess of the present annual consumption, so that it appears to be within the capacity of the cement factories now in existence to supply the requirements of the home market. On the basis of these figures the report states that there are grounds for misgivings as to the future of the industry if all the cement works now being projected are built.

NOTES OF TRAVEL.—V.

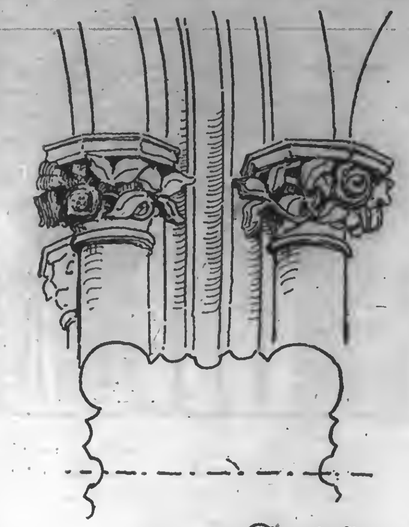
A flying journey on bicycles is not productive of careful drawing; but it was impossible not to make some notes, and they may be worth publishing.

Contemplating in a peaceful mood, on waking up in the morning, the bedroom cornice in my bedroom, in our inn, a Jacobean building, it seemed so thoroughly satisfactory that I thought a measured drawing of it would be worth something to readers of the Canadian Architect and Builder. The room had two windows on a long side. Over the windows, all vertical surfaces were dark, all horizontal surfaces white. Opposite to the windows this effect was reversed. On the short sides, which got a raking light, the whole cornice was blanched except the weathered soffit, which was a dark band. This variety was delightful. The breaking of the cornice around the chimney breast, at one end, was just right.



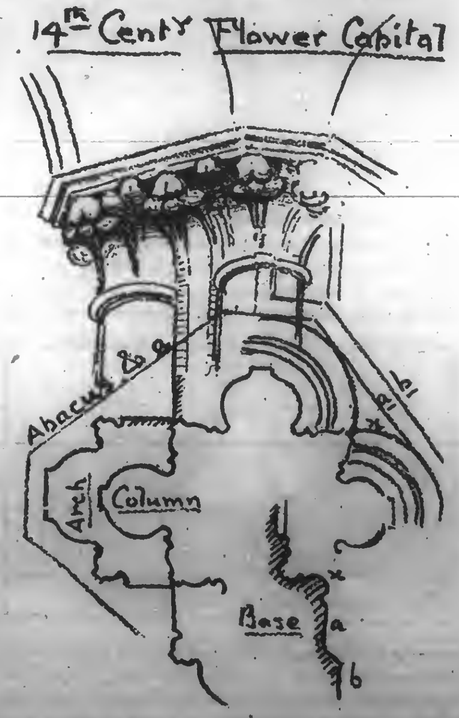
We visited a perfect Saxon church; but, in Canada, we have got ahead of the Saxons. The parish church, on the other hand, if one could bring it over, would be the finest church in most towns and the most interesting in the country. What, however, seemed best worth noting, because differing from other work of the kind, was a restored portion, in which the architect had, with success I thought, ventured to be original. Two columns had scrolls as shown above; said to have been a whim of the lady who paid for the restoration. The ribbon ends require judicious abstraction. (They were, in this case, given the comparative obscurity of the aisles). The bands were not in the least simulative of ribbons but good solid masses, 8 inches deep, with a minimum projection of 2 inches beyond the surface of the angle shafts, which meant at least 4 inches out from the deepest hollow of the mouldings. The surface of the bands waved slightly, not to follow the line of the mouldings, but arbitrarily, for the sake of a varied surface. The jointing was a difficulty; it had to be jogged to avoid a feather edge, and was made as inconspicuous as possible.

The capitals of the restored part were also interesting; as being original, yet in perfect keeping with the style, carefully modelled roses, yet abstract enough for stone. The 14th century could do this sort of thing as well, or better, when it chose. A couple of days afterwards, among some beautiful "stiff leaf foliage" capitals (which were, however, not so stiff as they appear in the books but, on this occasion at any rate, full of life and gracefulness) the above flower forms appeared. The sort of clinging springingness with which they grow under the projection of the cap was well expressed.



Rose Capitals

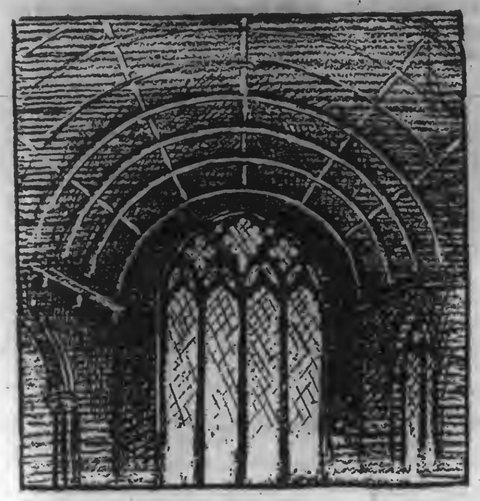
It is impossible not to become deeply interested in these beautiful white stone churches, but interest is qualified by doubt as to its immediate utility. The



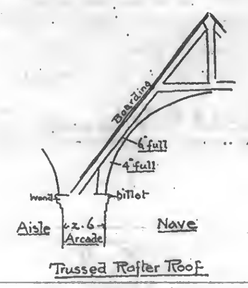
roof, however, which is commonly met with in village churches suggests application. It is a form which goes very well with a medium pointed window, and has a

NOTE.—We regret that the illustrations to the Notes of Travel in the September number were published without acknowledgment that they were the work of Mr. E. H. New, reproduced from a pamphlet printed by the Guild of Handicraft in connection with an exhibition of their work.

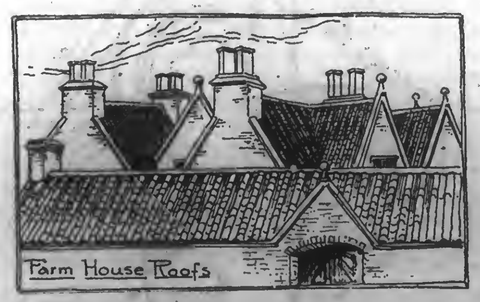
continuity of form that is as dignified as vaulting and, if anything, richer; quite apart from the barn-like effect of principals and purlins. It is unfortunate that



age cannot be made a condition of contract; unfinished oak, bleached like bones with age, goes admirably with stone and inspires respect from its venerableness. But I have seen a beautiful new roof of the kind by Mr. Bodley. It takes a thickish wall, if the curved member

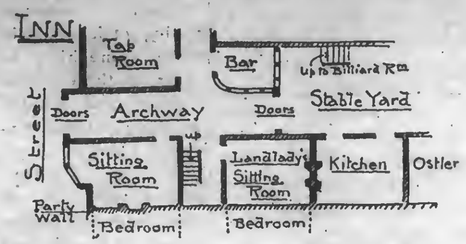


is to be flush with the wall, as it ought to be. The roof in the above section spanned about 25 feet and was a degree or so steeper in pitch than 45 degrees. There was a narrower aisle roof on each side (the window was at the end of one). This of course means



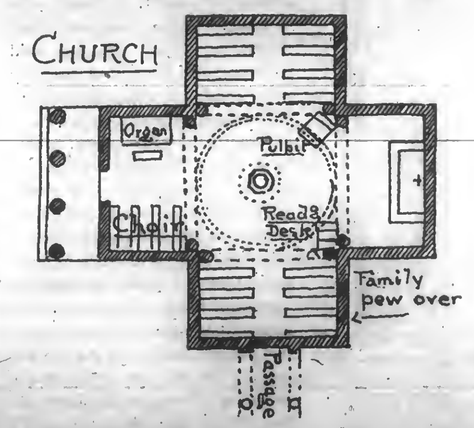
a couple of horizontal valleys of the full length of the church; but that is one of the privileges of this frostless country. It simplifies the roofing question and, as a consequence, complicates the roofs. There is no use in our imitating this kind of thing in Canada; though we cannot pass it in England without stopping to admire.

The mildness of the climate is still further exemplified by the plan of our inn, every room is practically out of doors; for the doors of the archway are never closed except at night; and, while they are open, even the upstairs rooms may be said to be out of doors; for the staircase opens off the archway, and there are no hall doors above. It is a case of dwelling in tents. In winter it



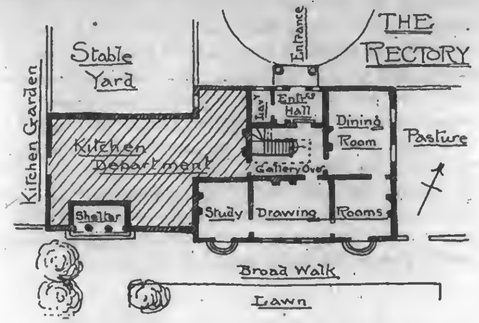
must be like a series of warm air baths, with cold plunges between: that is, if the rooms are warm.

On Sunday we went to a little Doric church connected by a passage with the hall. The church was a solemn little composition, but not big enough or comfortable enough to be really dignified. The crossing, under a dome, was about 25 feet square; handsomely paved in marble, and vacant; except for a little, lonely font in the centre. The crossing was probably a cube, and was domed with a semi-circle on top of semi-circular arches. The arms of the cross extended a little more than half their width and were barrel roofed. It was interesting to see how well this building was lighted by a small lantern in the dome and semilune windows at the ends of the arms. The glass was also coloured, though not



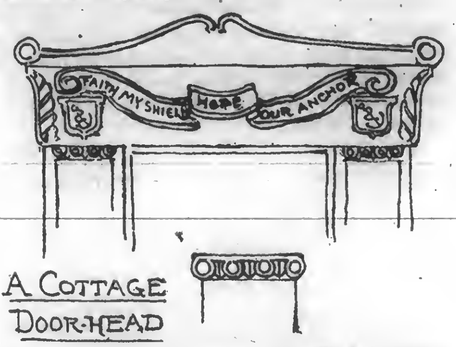
deeply. We dined at the Rectory, which had a good set of rooms looking southwards. The most interesting feature of the plan was a galleried hall which was roofed above the rest of the (two storied) house and lighted by circular windows in a clear story. There was a fine and well lighted wall space, above the gallery, for hanging large pictures. The land to the south of the house was the rectory glebe and let out for hay and pasture, excepting a lawn and gardens attached to the house. The gardens were enclosed by a stone wall, sinuous in plan for the sake of greater stability. It

was open to the suspicion of looking more knowing than it was. It looked as if buttresses would be better in every way. It was interesting to meet here a ha ha fence. The pasture, on the east, was enclosed by a stone wall; but, instead of running past the south front of the house, to enclose the lawn, this wall, when it came to the east line of the house, dipped underground and became the retaining wall of a wide ditch. As the ditch was invisible from the drawing room windows, the effect was of an unbroken slope of grass, stretching



away in boundless continuity to the rising and wooded ground of the park.

The hall, which we saw in the afternoon, is of the Italian period and dull; but size and stone are always something, and a stone flagged terrace, about 30 feet wide and 90 feet long, handsomely balustraded, with the valley of the park seen beyond, stretching away in a perspective of heavily wooded slopes, is a vision to remember as long as possible.



W. A. LANGTON.

A BUILDING COMBINE.

To the Editor of the CANADIAN ARCHITECT AND BUILDER:

SIR,—I have learned from a reliable source that some fifteen Toronto contractors who were asked to submit tenders for the construction of a new grand stand at the Woodbine race course, after laying their heads together, agreed on a uniform basis for tendering. It was further agreed that whichever one of their number might receive the contract must give the sum of one hundred dollars to each of the unsuccessful tenderers.

It is a well-known fact that there has existed for some time in Toronto a combination among heating contractors, the fact being clearly enough apparent from the character of the tenders.

Some architects have already brought in outside contractors to do their work, and express their purpose of following the practice to a much larger extent if such illegitimate methods of getting fancy prices are persisted in by local contractors.

I think it only right that this sort of thing should be exposed even at the risk of frightening persons out of the idea of building.

NOTE.—Results tabulated are the averages of six briquettes. The residue left on sieves of 50, 100 and 180 mesh were: Giant, 0.15, 5.4 and 21.2 per cent. respectively; Atlas, 0.1, 7.0 and 18.0; Union, 0.1, 4.6 and 10.2; Hoffman, 2.3, 12.4 and 21.9.

A heating boiler for steam and hot water, designed to burn coke, has recently been placed on the United States market by the American Radiator Co. The McEachren Heating and Ventilating Co. of Galt, Ont., have been manufacturing a boiler in which during the coal famine last winter, coke was successfully burned.

DOORS.

For the last few weeks we have directed our attention to the study of doors, pursuing a line of thought that we believed to be original. Imagine our chagrin when on reading one of the "Sketches by Boz," we found this pet idea or theory of ours had been made public years ago; but the dissappointment we experienced was considerably lessened when we reflected that Dickens himself had viewed in the same light the desirability of the design of the door portraying the character of the occupant. He states: "We are very fond of speculating, as we walk through a street, on the character and pursuits of the people who inhabit it; and nothing so materially assists us in these speculations, as the appearance of house doors. The various expressions of the human countenance afford a beautiful and interesting study; but there is something in the physiognomy of street doors almost as characteristic, and nearly as infallible. Whenever we visit a man for the first time we contemplate the features of his door with the greatest curiosity, for we well know that between the man and his door there will inevitably be a greater or less degree of resemblance and sympathy."

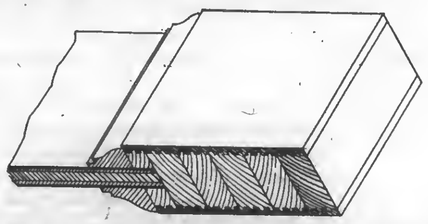
In designing the street door, did we ever for a moment study the individuality of the occupant? For instance, a five panelled, flush planted moulding, two feet ten by six feet ten door, would be most suitable for little spare priggish men, who are perfectly satisfied with their own opinions, and what can better bespeak the man of substance and genial hospitality, than a door three feet six wide, with raised panels and bolection moulded. Then there is the door solid below, with glass in the upper half. This is suitable to an innumerable class of people; the pretentious and vulgar divide the light into elaborate geometrical patterns, and glaze it with bevelled plate. Sometimes it is glazed with one clear light of glass— a standing invitation to all passers by to look with envy at the gorgeously furnished interior, and very occasionally we find it daintily screened with lace curtains, by the modest and retiring housewife, who timorously shrinks from the vulgar public gaze.

The types of street doors are innumerable and have a far reaching influence. If you ever find your client dissatisfied, or a man changing his habitation without any reasonable pretext, depend upon it, that although he may not be aware of the fact himself, it is because he and his street door are at variance; he is induced to move and seek a house with a street door more congenial to his foibles.

In studying this question of doors, we have come to the conclusion, that both the size and design of the door is more fixed than any other feature in an ordinary sized house. Let us take a so-called modern house; the drawing-room is designed in a style we will call Louis Quatorze, the library is Elizabethan, and the dining-room has a Dutch feeling throughout, and the hall, well we will make this Colonial, for it is necessary, if we wish our house to have all the modern improvements, that we treat each room in a different style. It is not a question of size or shape, or adaptability of the room, we must cram into it any style that is fashionable, if we wish to have a modern house with the latest improvements. Rosengarten has much to answer for in this particular, with his six hundred and thirty nine illustrations of various styles.

Let us now consider the doors opening off the hall into the various rooms. The framing of the door must necesarily show the same on both sides, and therefore, the design is more or less fixed. We must depend largely upon the treatment of the architrave around the doors, to give it the character peculiar to the style.

Another point to consider is the kind of wood in which the various rooms are finished, but this problem is more readily solved than the previous one, for in these days of perfected machinery, the door can be veneered with any kind of wood. We have lately seen a very ingenious method of applying the veneer by Messrs. Gilmour & Co., Trenton, Ont. The core as in the veneered door is built up in three or four pieces, but both the core and the veneer are grooved and fit tightly into each other, thus, apparently giving three times the glueing surface there is in an ordinary flat veneer; the panels are built up of five ply stuff with the grain running in different directions.



Some two or three years ago we were discussing this question of veneered doors with a builder from England, and it was with the greatest difficulty we got him to admit that a built up veneered door under certain conditions, was superior to a solid door. Even when he was finally convinced, he wound up by saying it was a sham.

Obviously, however, it is no more a sham than a stone front with brick backing. There is no country in the world, where the climate is so varied as in this Canada of ours, and we know that solid doors do not always withstand the extremes of dryness and humidity. The dry steam heat in our buildings during the winter months, and the humidity of the summer and fall, frequently cause solid doors to shrink and check, whilst the advantage claimed for a veneered door is that these varied climatic changes have little or no effect upon it. As to its being a sham, we would remind our English friend of Emerson's statement: "It is a rule of largest application, that in the construction of any fabric or organism, any real increase in fitness to its end is an increase of beauty."

It is reported to be the intention of American Plate Glass manufacturers to make a heavy reduction in prices with the object of crippling their foreign competitors. The announcement is said to have caused consternation among the Belgian glass manufacterers who have hitherto done a large export trade with the United States.

In Dawson City water for domestic purposes is said to be supplied through machines operated by dropping a coin-shaped slug into a slot, in order to avoid the difficulty arising from freezing of house service pipes in that cold region. Five gallons are delivered at a time. There are few if any house service pipes.—Engineering Record.

PRODUCTION OF BUILDING MATERIAL.

From the annual report of the Ontario Bureau of Mines for 1901, it is learned that the output of building and construction materials has for some years been steadily increasing, and the aggregate for 1902 was in excess of that of 1901, though in one item, that of common brick, there appears to have been a falling off, presumed to be due to the average price having advanced from $5.90 to $6.41 per thousand.

The following table gives the statistics of the production of building stone, rubble, etc., lime, common brick, and pressed brick and terra cotta for the five years 1898 to 1902:

Material.	1898.	1899.	1900.	1901.	1902.
	$	$	$	$	$
Building stone, rubble, etc	750,000	667,512	650,342	850 000	1,020,000
Lime	308,000	535,000	544,000	550,000	617,000
Common brick	914,000	1,313,750	1,379,590	1,530,460	1,411,000
Pressed brick and terra cotta	100,344	105,000	114,419	104,394	144,371
Totals	2,072,344	2,621,282	2,688,351	3,034,854	3,192,371

Other clay products consisting of drain tile, paving brick, sewer pipe and pottery, were made during the year to the value of $604,280, a slight decrease from 1901.

A MACHINE FOR LAYING BRICKS.

An Englishman, John H. Knight, has designed a machine for plain brick laying, shown in the illustration. Vertical posts are set in the ground about 15 ft. apart. Adjacent to the wall to be built to these posts is secured a wooden girder upon which is screwed a 6 in. x ¼ in. steel plate. This steel plate forms a bed on which the machine runs. The driving mechanism consists of a toothed pinion meshing with a pitched chain along the girder, motion being given to the pinion by gears and handle. A guide bar secured to the girder forms the straight-edge for the face of the bricks which are fed to the machine by hand. A pawl operated by a separate handle serves to press one brick back against the

Brick Laying Machine.

previous brick. Each brick as it moves back pushes a ridge of mortar in front of it, so that the vertical joint between the two bricks is filled. The mechanical bricklayer pats the top of each brick, this being done by a spiked roller which derives its downward pressure from a stout spiral spring regulated by the adjusting screws. The mortar is run out by hand in front of the machine. As each course of bricks has been laid the girder is lifted by hand 3 in. Holes are bored in the upright posts to form catches for a lifting lever. Two men and a boy can operate the machine. One man spreads the mortar, the second feeds the machine and the third operates it. Mr. Knight claims that the machine will lay down from 500 to 600 brick an hour.

MR. PERCY E. NOBBS.

We are privileged to present to our readers the accompanying portrait of Mr. Percy E. Nobbs, who recently entered upon his duties as Professor of Architecture at McGill University, Montreal, in succession to Prof. S. H. Capper.

Mr. Percy E. Nobbs.

Mr. Nobbs is a native of Haddington, N.B. His earlier years were spent in Russia, where he received his first artistic instruction at the School of Design, St. Petersburg. In 1887, he entered the Edinburgh Collegiate School, leaving in 1893 to take the Arts Course (new regulations) at Edinburgh University. During his school and college years he took various art and technical classes at the Heriot Watt College, the school of art and the new school of applied art, all bearing on his profession.

In the spring of 1896, Mr. Nobbs graduated as M. A., and travelled abroad before becoming an articled pupil with Mr. R. S. Lorimer, A.R.S.A., of Edinburgh, with whom he remained four years. In 1900, he won the Tite C. Prize at the R.I.B.A., and passed his examination for A.R.I.B.A., afterwards spending a further period in foreign travel and study.

In 1901 he entered the service of the London County Coucil, where he gained much practical experience of building operations. Subsequeutly he became chief assistant to Mr. A. Hessell Tiltman, F.R.I.B.A.

In January of the present year Mr. Nobbs was awarded the Owen Jones Travelling Studentship (£100) for a scheme for the decoration of a church in mosiac.

He is a member of the standing Committee on Art of the R.I.B.A., and the author of a number of valuable papers on professional subjects presented before the Edinburgh Architectural Society.

In assuming the chair of architecture at McGill, Mr. Nobbs will endeavor to give practical form to ideas already clearly defined, and which it is hoped may improve the status of architecture and of architectural workers in Canada.

BY THE WAY.

The memory of prominent events and persons who have figured couspicuously in national affairs, is being perpetuated by the designations given to streets in London. Some of the newer thoroughfare bear such names as Pretoria, Joubert, Hawarden grove, etc.

\+ + +

I observe that Lieut. Peary, of the United States Navy has been granted three years leave of absence to enable him to make another attempt to reach the North Pole. If Mr. Peary does not achieve greater things on this than on his last two or three expeditions, our own Captain Bernier stands a good chance of getting to the pole first.

× × ×

We find a good many faddists among architects, but if reports be true they are eclipsed by a certain Swiss silk manufacturer, who has had built for himself a counterpart of the Swiss lake dwellings exhibited in the Zurich Museum. This architectural freak is built on piles in Lake Constance a distance of 200 feet from the shore. Around the house is a gallery 5 or 6 feet wide. The exterior of the walls is covered with osiers and lime. The floor is of plaster and the roof is thatched. Instead of glass, bladder is used. Wood of the yew has been employed as far as possible.

× × ×

I learn from "Indian Engineering" that the director of railway construction of the Public Works Department of India has issued a circular to engineers employed on large works asking them to experiment with the process which is said to have been recently discovered in the United States for increasing the tenacity of clay by mixing it with a liquid obtained from boiled straw. Mention of this discovery was made in a recent number of this paper. It is said that this process was employed by the ancient Egyptians in the manufacture of bricks, and that by this means the strength of bricks can be materially increased.

× × ×

They have a quaint way of telling the time of day in the Roothings, according to an Essex contemporary. A working man who was walking from Ongar towards Dunmow passed through a village about mid-day, and, wishing to know the hour, asked an old dame who stood at her cottage door if she could tell him the time. "Yes, that I can, boy, if you wait a minute," she exclaimed. She at once hobbled to the end of the row of tenements, and glancing up at a tall cottage chimney, athwart which the rays of the sun fell, said, "It wants just a brick and a-half to one." The surprised traveller, though a bricklayer by trade, had no knowledge of brick chronology, and enquired how many bricks went to the hour. The old lady explained that there were three bricks to the hour; and thus the time would be 12.30 p.m. The mystified man made off to the nearest wayside tavern for his mid-day meal, and he found that the cottage's sun-dial was true, for the hands of the inn clock pointed to half-past twelve.— British Clayworker.

× × ×

Up among the arches of the great new cathedral at Westminster a "twittering" may be heard which, on investigation says the Builders' Record, is found to proceed from a score of young ladies enveloped in overalls. These are the workers on Mr. George Bridge's mosaics —in the chapels of All Souls and of St. Gregory and St. Augustine on either side of the vast nave. Mr. Bridge finds that the young ladies suit his needs admirably, but it must not be supposed that they are there without training. "I have ladies come to me sometimes," say Mr. Bridge, "who think they can set to work at once and earn two or three pounds a week. But that is, of course, absurd. There is a great deal of technique to be mastered, and I estimate that a fairly clever worker needs two years' experience before being put on figure work"—these young ladies have been through the schools and drawn from the "life," so that they are able to handle the mosaic in an intelligent manner. Mr. Bridge's first pupil was his wife, who succeeded so well that he decided to engage other female workers; until we find him here in the cathedral directing quite a school of them. The practice of architecture as a profession for women receives periodical attention but, with a few exceptions, never becomes a reality. For ourselves we do not think it ever will while contractors are men, not always gifted with the tongues of angels; but there is surely a field for women in some of the applied arts connected with architecture where, indeed, the subtler touch of the female hand and the more delicate gauge of the female eye may prove a boon—a possibility to which Mr. Bridge's practical experience gives much hope.

NEW METHOD OF CHIMNEY CONSTRUCTION.

As a substitute for the special device called "wagons" usually employed in the construction of chimney flues in Paris, M. Morel suggests the use of a special form of brick which while strictly conforming to the Police Regulations admits of easy and quick construction and close union of the various parts of the flue. The British Clayworker describes the method thus: The sides are perpendicular to the horizontal surfaces, except one side, which is at an angle of 30 deg. to make a joint between two flues. To enable crossing of the other straight joints one part of the brick is longer than the other part. The bricks are laid as follows: A brick being in place, a second is turned in such a way that the two surfaces are applied one against the other, forming a joint with mortar. Thus a first course is laid, and, as the joints have to be crossed, the bricks in the second course are laid on the two bricks mentioned, and turned so that the large sides of the bricks in the second course are applied against the small sides of the bricks in the first. The inclined joints of the second course are thus in an opposite direction to those of the first. When the flues bend, the bricks are usually laid on different surfaces in steps, forming places where the soot can accumulate to be removed when the chimney is swept. To avoid this inconvenience the flues must be made of plaster or cement. M. Morel employs a special brick with inclined surfaces, which can be utilised with ordinary bricks. A course of bricks is laid and between two courses of these bricks the new bricks are laid, which have two oblique sides. Thus a flue is obtained not having an arrangement in steps, but a sinuous surface, requiring no facing, from which soot can be easily removed.

A new building by-law recently adopted by the city of Minneapolis compels fireproof construction of all public and quasi-public buildings of over three-storey dimension, and prohibits the use of cinder concrete.

METHODS OF REMEDYING DAMPNESS AND EFFLORESCENCE IN WALLS OF BUILDINGS.

The following on the above subject is extracted from a work by Adolph Wilhelm Keim, German Chemist:—

Most of the methods which have been proposed for curing damp walls have been based on the use of waterproof plastering or paint, or depend on the principle of employing hollow walls, with or without ventilating apertures. The former device may in certain cases fulfil the desired end, although as a rule it merely hides the mischief for a time and actually aggravates it. The plan of using hollow walls with ventilating channels, whilst more correct in principle, is both costly and difficult of application to old houses.

Vaudoyer has the following remarks on these two methods: Imagine the wall of a basement to be affected by moisture, and to exhibit efflorescences on its external surfaces; it would be of no use to try to shut the damp into the wall, we must rather afford it an opportunity of being dried by the air, whilst endeavouring to remove the cause. With this object air channels should be inserted in the walls above the ground level, cellars may be excavated where none already exist, the inner and outer plastering of the walls may be removed, and any precautions similar to those which are employed in new construction may be adopted. In cases however, in which these precautions are no longer possible or when in spite of them the effects of dampness still continue to exhibit themselves, recourse must be had to other means, such as the following: To prevent the moisture which is present in the wall of a building, and shows itself on the interior surface, from influencing the air of the apartments, the best plan is to face the wall with hard tiles, set on edge at a distance of about an inch from the face of the wall so as to permit a circulation of air between the wall and the inner casing. It is beneficial to give the inner surface of tiles a coat of asphalt, especially those which are tied to the wall, whilst the outer surface may be coated with plaster(?), which when perfectly dry can be painted or plastered, or, since wall-paper does not adhere well to plaster of Paris, it may be pasted upon coarse linen.

This system would afford all needful security, and further harm would arise from the moisture even if it still remained in the wall which was originally affected by it; but even in the wall itself it would be markedly diminished by the ventilation which would be established between the wall and the inner casing. A less expensive expedient would be to erect wooden battens against the wall, with diagonal ties, to nail laths upon these, and then plaster the laths. This would give a thin partition, isolated from the wall. The wooden battens, being in contact with the damp wall, would have no great permanence; they should at least be well tarred, and have sheet-lead interposed between them and the wall; a free circulation of air is, moreover, absolutely necessary. Wooden wainscoting amounts in fact to an isolated partition, and it is certain that the partial, or, if necessary, the complete lining of the walls of a room with wood is a great protection against damp; nevertheless, the ill effects of moisture on the building itself will still have to be feared if a free circulation of air is not provided for behind the wainscot, the back surface of which, moreover, should be well tarred.

Although the system which has just been described is to be preferred to any other, it nevertheless has the disadvantage of reducing the size of the apartment considerably; we have therefore to consider whether other devices may not in some cases be adopted.

In cases where the wall in question is an interior wall separating two apartments, both of which require to be screened from damp, there is no alternative but to adopt the system of isolated partitions; for if any coating impervious to moisture were applied immediately to the wall, the result would simply be to enclose the damp in the substance of the walls, and would promote a destructive action which would be all the more detrimental because it would escape observation. But where the damp shows itself in only one of the rooms, it would seem that to suppress it on that side of the wall would drive it to the opposite one, where, however, it would not be so harmful as in the former case, because at that side the air might be relied on to evaporate it to a large extent. In such a case it is better to avoid the use of an isolated partition, and to apply directly to one side of the wall the waterproof coating which is regarded as the best protective. It must, however, be admitted that few of these will long maintain their coherence with a wall which is perpetually damp. Framed partitions take such a coating more readily than walls built of stone. The material selected for application should, if possible, be one that will penetrate into the substance of the wall. Such an application may also be employed for the inner surface of an exterior wall, if this has a favorable aspect. For if one of the surfaces is exposed to the influence of the air, the damp will be able to escape from the whole thickness of the wall.

Although this plan presents indisputable advantages in some cases, there are others in which the wall may be coated with glazed tiles, affixed with good mortar; or, in rooms where a tiled wall is not appropriate, the rough side may be left exposed, and can then be covered with paint and any desired style of ornamentation. In some instances, tiles saturated with asphalt may be used; in others the whole surface may be covered with thin sheets of lead. The chief difficulty in using metallic plates is to find a suitable material for attaching them to the wall. This is required not only to harden readily, but also to adhere firmly to both the surfaces to which it is applied.

It would be superfluous to remark that a damp wall to which cement, or any other waterproof material, is to be applied, should first be stripped of its former coating, and allowed to dry for some time before the new coat is laid on. And it must further be remarked that rendering with mortar consisting of hydraulic lime and sand gives a surface which is quite unsuited to receive a coat of oil paint, since the latter would not adhere well, but would speedily peel off.

C. G. Demich has proposed some extremely complicated ventilation attachments, which are so costly that scarcely any one would introduce them into old buildings, on which account I pass them over. But he also gives the following method for protecting against damp:—

An excellent method (he says) of preventing the escape of water vapour from damp walls is to cover them with small glazed clay tablets. These tablets, which can be made by any potter, are about ⅞ inch square and ⅜ inch thick, and are glazed on one side. They are attached to the wall, with the glazed side outwards, by good mortar or plaster and small clamps. A wall covered with such tablets has not an unpleasant appearance, but when lighted up at night, the glitter is injurious to the eyes. To avoid this the tablets may be fixed with the glazed side towards the wall, the rough side coated with a thin layer of fine cement, floated, and papered. When the damp is not excessive, the wall may be covered in the same way with old window glass, then floated with cement, and papered.

DRAWING AND ARCHITECTURE. —I.

By Prof. Percy E. Nobbs.

Note By The Author :—These three short papers on (1) Drawing and Architecture ; (2) The Styles of Architecture ; (3) Material and Design ; are intended as an introduction to the study of Architecture for students assumed to possess no knowledge of the subject, and the themes are treated with regard to their bearing on study only. They were delivered at McGill University this September.

As a beginning to our first winter's course in Architecture, we shall devote three lecture hours to the consideration of what may be called the first principles, not of Architecture, but of Architectural Studentship, before taking up our studies in Construction, Theory and History. It is not likely that my students will at once fully understand all these principles imply, for it is very difficult properly to express any ideas connected with our art in words,—written or spoken.

In the "Elements of Drawing," Ruskin says to his reader :—"If you wish to learn drawing, that you may be able to set down clearly and usefully, records of such things as cannot be described in words, either to assist your own memory of them, or to convey distinct ideas of them to other people, * * * then I can help you, or which is better, show you how to help yourself."

Now it is with "such things as cannot be described in words," that we have to deal,—after all a specification gives a very poor idea of a building, even to the expert. But happily we have in drawing, a way of expressing architectural ideas and a way capable moreover of the utmost refinement of expression.

To-day we shall make a short enquiry into the relations which subsist between the art of drawing and the art of building.

The modern architect must draw, and draw well. We shall have no difficulty in coming to that conclusion. Before going further, however, I would impress it upon you as students, (and this will be the burden of my song, till such time as I have done with you,) that we must never regard drawing as an art worth cultivating for its own sake. Let us take all the pleasure we can in drawing well, and the more pleasure we find in it the better we shall draw ; but we must never forget, that it is the rightness of the subject matter alone that is of any importance to the architect. True, a neat clean drawing is more pleasant to handle and peruse, than a dirty or careless one ; but it is only so far as the facts on the paper are unimpeachably true, are easily understood, and have reason in them that the drawing is worth anything. The very great majority of students' drawings are worth less than half the value of the paper they are on, because both sides have probably lost their original whiteness by the time the drawing is finished. When we have come to regard our drawings in this light,—as damaged paper in no way beautiful, certainly not decorative, but, possibly a little useful,— then the first step has been reached on the stair which leads to the halls of architectural learning, and not until then.

Truth in a drawing is the only thing worth paying for, and he is paid best who puts most truth, with given labor, on a given area of paper. Speed in drawing is the only thing that makes it possible to earn a living as a draughtsman, and we may here remember with profit, that on leaving McGill we have several years to live as draughtsmen, before we can design so simple a thing as a rabbit hutch in the really, best possible way. Success in this profession, on which we have embarked, possibly with a very light heart, depends to a great extent on our drawing ; for unless by this means we can be of real use to an architect on leaving college, our progress will be slow, and practical experience will come in a meagre measure, even in spite of enthusiasm and intelligence. In a word, on the lower rungs of the architect's ladder, there is no room for the man who cannot draw.

Now it is the practical experience that we gain in an office that is the really essential thing for the designer—that and the study of the work of those who have gone before us. Accomplished draughtsmanship is only accidently essential—it is the means by which we attain to the really essential things.

George Edmund Street in one of his Royal Academy lectures commented on the fact that "Men built magnificently when they drew but poorly." It was only in quite modern times that it became necessary for a paper version of what was proposed to be built, and our business today consists very largely in the manufacture of paper versions. When we study the history and development of Architecture we shall realize how tremendous was the change which the Art of building underwent owing to the substitution of this indirect process, (by which one man makes himself responsible for the form and size of every part of a building from a tower to a turnbuckle), for the simple methods of former times.

We must not understand by this that the Gothic constructors did not scheme things out on paper or even that they did not use scale drawings but extant specimens of drawings and work show how very little attempt was made to make paper drawings give anything like a true idea of the real buildings. Drawing was unnecessary then and architecture had certain qualities as a result to which it is beyond the power of modern methods to attain. We must not let our reverence for ancient things blind us to the fact that something also has been gained by the genesis of the architectural draughtman. The men who were responsible for the Mediæval Cathedrals did not sit on a three legged stool in a city office and superintend a score of buildings at once—some of them hundreds or even thousands of miles away.

George Edmund Street somewhere in the inspiring set of lectures above referred to denies that the pencil has any magic power to help the designer when ideas run out or refuse to curdle into form before what the Scotch call the "mind's eye." His experience is not that of the rest of us, and it has even been hinted that had he allowed the pencil to guide him occasionally instead of guiding it so strongly his designs would not have suffered.

The point we are endeavoring to make is this, that facility in drawing—speed in execution, accuracy and sympathy in delineation—is an enormous help in design by the indirect process of paper drawings. This is especially so when we have recourse to the method of trial and failure i. e., drawing in and rubbing out till we satisfy ourselves that the parts of the thing are of the right size to give the impression we desire our work to convey (for the face of a building is like the face of a man in this that the least appreciable displacement of its eyebrows or the exact curl of the brim of the hat alters the whole expression). Even at the initial stage of a design drawings to scale conveying vividly to the practiced mind the idea of the actual bulk of what is under consideration are of utmost use, as till we can realize the size of the whole it is useless to materialize the proportions of the parts. And the longer we work the more we shall realize that design is a question of proportion,—of the sizes of things in relation one another, and that that indispensable but subtle instinct called the sense of scale, can best be cultivated by drawing.

Ruskin says in the work above referred to which it were well for all to read. "Do not therefore think that you can learn drawing any more than a new language, without some hard and disagreeable labor. But do not on the other hand, if you are ready and willing to pay this price, fear that you may be unable to get on for want of special talent." It is indeed true, that persons who have peculiar talent for art, (and by art Ruskin usually means drawing only.) Draw instructively and get on almost without teaching, though never without toil. * * But I have never yet in the experiments I have made, met with a person who could not learn to draw at all ; and in general there is a satisfactory and available power in every one to learn drawing if he wishes, in a decent and useful degree, if his lot in life requires him to possess such knowledge."

Given patience on the one side, and right teaching on the other, the draughtsman can easily be made if he is not born.

To speak personally, my function here is to see that you draw the right kind of things, rather than that your drawing is well done ; but incidentally, I shall, I hope, be able to give you such hints with regard to manner and method of work, as may help you to get the utmost good from the subjects you will study graphically. Later on when the A B C of our architectural language has been learned, in the only way in which an A B C can be learned,— by putting it down on paper,— later on, I say, we shall group the letters into words, and the words into sentences—grammatical sentences, I hope, with meanings in them.

The things that we shall study are the works of our predecessors from "Delos up to Limerick," and to that end we have here a truly magnificent collection of slides, photographs and books, for which we have to thank the wise generosity of Sir William McDonald, and the deep scholarship, sound taste and energy of Professor Capper.

Now we might exhibit, peruse and dilate upon the beauties represented in this collection for weeks on end, without getting further than a general agreement as to the wonder of all this fine old work. The moment we begin to draw examples however, we begin to solve the mystery of how the effects we admire are obtained and what are the real relative proportions of parts which look perhaps equal in our views upon the screen.

Moreover, it is only by drawing that our knowledge of the detail and mouldings of various periods attains to that definite

and concise degree which makes it possible at a glance to know the date of a piece of old work ; and although it is quite immaterial for the designer to know what bishop or king endowed a church or build a chapel, the evolution of past architecture must be understood before a broad and sound view can be taken of the evolution that is going around us to-day, and dates are the milestones in this study. Therefore, on all accounts let us be patient and draw hard, much, truly and finely, and bear ever in mind that for us it is a means to an end, not an end in itself.

So that the facts be true, and the thoughts be right, the handwriting of this lecture is a very minor consideration. Not so in the "handwriting" of our true professional language ; on the technique of our drawing, depends the amount of fact which a given sheet, nay, a given line, or a given dot may have power to convey. Take pride, therefore, in how much truth, both in degree and quantity your drawings contain, and as little pride as your temperament will permit in the intrinsic beauty of your drawings, for, therein lies a deadly snare, as every draughtsman knows to his cost.

ARCHITECTURAL PRACTICE, REAL AND IDEAL.*

By J. S Gibson.

There are many amusing and curious ways of obtaining a practice, and for all of us it is a serious question to determine how to start on our career. But it is to be settled at an early stage, or else it will effectually settle us. Some cut the Gordian knot by leaving the ranks and embarking into the maelstrom of "trade" ; these are wise but inartistic ones. Some rely on the artistic blindness of the general public, and run lucrative drawing manufactories on business-like lines. These are the shrewd and "practical" ones. Some have relatives who are something big in the City of finance or Society, and these push their architectual appendages in the same manner as they do shares, or officers in the army. What Lord Melbourne said about the bestowal of the Order of the Garter, that "There's no damend merit about it," we may safely say that in reference to the practice of these fortunate ones. Some drift into that refuge of mediocrity, an official appointment in a Government office, and in the Office of Works, or such-like departments, do what they can to spread the commonplace over the land ; these can hardly be said to practise, either really or ideally. Some enter into competitions, throwing all their energies and skill therein, in the hope that merit will be rewarded. These are the sanguine ones, and sometimes they are not disappointed. Some enter into partnerships with clever men of business, who "manage" the clients while they manage the office. These are the timid ones, likeable fellows who think the chief end of life is to get a cornice perfectly proportioned or a skirting-board properly moulded. Some attach themselves to the land, and, backed by financiers, erect enormous piles of vulgarly commonplace type, whose chief quality is to bulk, and whose erection in some slight degree justifies the short leasehold system of land tenure ; these are the wily ones. Some develop an absorbing interest in rights of light, and devote precious time to the intricacies of party structures and then pass away full of years and riches ; these are the canny ones. Some renounce art and become crafty, finding that the public will pay more willingly for the abnormal than the artistic ; these denounce style, balance, composition, rythm, grace, and are sharp-sighted leaders of the blind. Some determine to live for art's sake, and usually die for it instead ; these are the foolish and artistic ones.

These are but a few of the thousand and one ways of practising our profession, and each of you must one day settle this great question for yourself.

Turning to the realities of practice one may say "happy is the man who knows nothing of them," for the whims and vagaries of the client are sometimes as difficult to deal with as the prejudices of the architect.

Among the first troubles likely to assail you are the reconcilement of the wants of the client with the amount of money he is willing to spend. In this matter it is well to show as kindly as possible the impracticability of expecting 5,000l worth of accommodation for 3,000l cash. Never estimate your buildings too low ; it will prove easier to have a margin to meet the changing views of your client, rather than a deficit to ask him to wipe off.

Having satisfactorily settled the money question, you can, with a merry heart, set about the designing of your house ; and if your client expresses a strong preference for any unusual disposition of rooms, you must give this your very best consideration, for, after all, he is the person who has to live in them. If you have hit on any particularly good arrangement, do not throw it at the good man, but lead him gently to it, and thereby gain his approval, for this is more often won by strategy than by force. Always be ready with examples of similar cases, and if these are already known to your client so much the better, for then he feels on safer ground ; all clients prefer experience to experiment. When discussing any question never imagine that force of language will atone for lack of reason. You will often find your client expressing his views on the architectural styles, and, if he desires you to design him a house which shall be Palladian Renaissance outside and English Gothic inside, do not regard him so much as a lunatic as one who requires careful treatment, as his appetite for styles may be omnivorous.

Having matured your design and written your specification, do not think that your worries are ended. Under the present system of competitive tendering for work, you may find yourself face to face with a builder who solemnly assures you that Smith's blue lias lime is much stronger and better than Brown's Portland cement, that drain pipes are best jointed with clay, and that footings should rest on the solid earth without the intervention of any concrete under them. Should you meet such a man no doubt you will inform him of your good old crusted prejudices, and stick to the specification. Having taken a firm standing in your dealings with a builder of this kind, maintain this attitude to the end, and you will generally succeed in getting a creditable job for your client, although at some trouble to yourself. But we must not forget that we are paid for the trouble involved in getting our buildings properly erected, as well as for designing them.

One of the surprises of practices in their early stages, is the extraordinarily easy manner in which variations can be made on contracts during execution, so that when the accounts come in they often surprise the architect more than any other person. The apparently innocent suggestion to "omit the moulded beam and side brackets" over an opening, and just "put in a couple of semi-circular arches with a column and two pilasters," has in some mysterious way, been expanded into about five pages of a bill of extras, the total of which makes the architect gasp. The only safe rule in all these matters is to make a drawing and to get a price fixed before any work is done. If, however, you have made the variation without a price having been previously fixed, you may rely upon one friend in your extremity, the quantity surveyor. He is the man who can pull you through. How he does it I do not pretend to know; perhaps he has no bowels of compassion as far as builders are concerned ; perhaps there is some free masonry of which you and I are ignorant ; but at any rate, he will usually succeed in making a bill more palatable to your client and yourself, and we cannot be too grateful to him for these services.

In your dealings with your client, as with your builder, make up your mind on the matter in hand, and never depart from your determination. Do not be so foolish as to expect to get your own way always ; you will be a lucky man if you get it occasionally, but if you show signs of indecision of character, depend upon it, you will never get it at all. Should your client, upon any vital matter, prefer his way to yours, let him clearly know that the responsibility for success or failure rests on him.

If your work be at a distance, and frequent visits are impracticable, do not be surprised at the variations the builder will quite innocently make on your designs. Some of the most charming results are often thus accidentally obtained.

Years ago a fellow architect said to me, "It's a poor design that does not admit of improvement in execution," and the ripening experience of the translation of drawings into solids will suggest the variations that are improvements. Do not worry too much about the finish of your drawings. The work itself is the heart of the matter, and, above all things, do not over elaborate the details of your drawings. A multiplicity of detail does not ensure a fineness of quality, and I had rather see one good architrave round every door of a house than an abundant variety of commonplace sections. You may dash off sketches of facades and interiors ; many of the happiest inspirations are the most evanescent, but as you grow older you will find it harder to let your full sizes go out of the office. These are the final stages in your part of the work and by them you will be, in a great measure, judged.

The requirements of modern civilization are so varied and complex and we live at such a rapid pace, that even the practice of architecture has been invaded by "specialists" who apparent-

* Abstract of a paper read before the Architectural Association in London.

ly imagine that a thorough knowledge of technical details will compensate for a lack of knowledge of the art of their profession. There is hardly any modern pretenders so lacking in justification by their works as that of the architectural expert or specialist. It may be argued that this is the only scientific method of dealing with modern complicated requirements; if so, its scientific efficiency hardly justifies its artistic barrenness. My earnest advice to you is to make your practice cover as wide a field as possible; shun specialism, however lucrative it may appear.

Within the scope of a moderate practice you will find extensive demands made upon your knowledge. Apart from the capacity to design, there must be the ability to design within the limits imposed by the requirements of the Building Acts of London, Provincial and Urban Authorities, to utilize in the best way the properties of steel, iron, and concrete, as well as the older building materials, stone, brick, and wood. You must also be conversant with the latest patents in pavement lights, have a knowledge of the virtues of glass tiling, know the strong features of burglar proof sash fasteners and give a warranty that your door knobs will never come off the spindle.

Besides this all-embracing knowledge that is required of us, a new danger is rising up, born of our advancing civilization. We are now in the glorious days of trusts and combines, when everything is on a colossal scale, especially the capitalization, and no doubt the inherent poverty of our profession is the only thing that, thus far, has saved us. Think of the waste of energy going on in the artistic world to-day, of painters and sculptors creating pictures and statues and trying to find a market for them—often in vain. Imagine the immense saving that could be effected by a Pierpont Morgan buying up the output of Sargent, Whistler, Shennon, Swan, Guthrie, Laverv, Brock, Gilbert, Frampton, and putting these artists on regular employment at a fixed wage, under healthy conditions in a factory complying with all the requirements of the Factories Act, whatever these may be. Saved from the rapacities of the "dealer," in Bond street and out of it, what magnificent works these men would turn out, while the public would no longer have to go to the dealers to be advised as to the safest thing into which they might invest their money, as if works of art were mining shares and dealt in for the rise or fall of an active market. The only bar to the success of such a scheme comes, strangely enough, from the artists themselves.

I have talked so long on some of the realities that little time is now left in which to speak of the ideal practice. It is like the promised land—before our eyes, but never beneath our feet. Of what would such a practice consist? we ask, and every one's temperament will dictate a different answer.

The ideal practice must surely be that which ensures the evolution of the individual in the advancement of his art. To progress along parallel lines with your art must be a desirable thing, though it can hardly be said that, as a rule, our practice affords many facilities of this kind. Some requirements necessary to this end are common to many of us; these may be summarized as follows:

Work which is congenial to our temperament, and in which a healthy interest may be taken.

Time to think out our problems as a whole, and evolve slowly every detail. Absence of all "rush and worry."

An appreciation of the good points in our designs by those for whom the work is done.

A few assistants, good men and true, who will carry the knowledge gained a step further on their own account.

I could guess the young practitioner's ideal to be, that his buildings would turn out as fine as his conception of them, but the hard facts of reality destroy the charm of those imaginings.

I could guess the middle-aged practitioner's ideal to be, to begin again, with all the vigor and enthusiasm of youth, coupled with the matured experience of his years, but this combination is impossible of realization.

I could guess the old man's ideal to be, to be spared to practice for a few years that great art to the threshold of which many years of travel has brought him, but the inexorable summons comes, he steps across another threshold, and the door closes behind him for ever.

As far as the necessities of living will permit us, I think we should do all we can to realize our ideal practice, to advance the science and art of our calling, to do justice to our clients, our builders, and ourselves, and to uphold the honor and dignity of our profession.

PRIZES FOR ENGINEERS.

The Austrian Minister of Commerce has offered prizes of £4000, £3000, and £2000 for the three best designs to be submitted, showing methods of raising and lowering canal boats for an elevation of 131 feet, with the least possible consumption of water, in crossing the watershed between Prerau (Moravia), the head of the March basin, and Altendorf, the head of the Oder basin of the Danube-March-Oden Canal.

The method of accomplishing the object is to be left entirely to the competitors, who are also at liberty to submit proposals for constructing the works in accordance with their designs, so that the competition should appeal to a wide circle of engineers. If the execution of the work is not entrusted to the person whose design is adopted, a premium of £8000 will be given to him, in addition to the prize, when the successful operation of the contrivance has been demonstrated. Information for competitors will be furnished gratis by the commissioner for the construction of water ways at Vienna and by various provincial governors of the Empire; and by various Austro-Hungarian embassies. Plans and drawings must reach the Minister of Commerce by March 31, 1904.

PRESERVATION OF STEEL BUILDINGS.

From a report by Mr. Jas. P. Whiskeman, Assoc. M. Am. Soc. C. E., to the Superintendent of Buildings of New York, giving the results of a careful examination of the Pabst Building, the following deductions are made relative to the conditions necessary to the preservation of steel structures:—That the preservation of steel depends mainly on the protection afforded by paint, or the encasing of members in concrete or lime mortar, and that steel can resist oxidation when these protective coverings have been thorough; that paint is not always reliable in damp walls; that cast iron withstands rust better than steel. The connections of iron and steel are most liable to be attacked by rust, and these should be well painted or covered with a material like cinder concrete. All the unpainted steel-work, tie-rods, hangers, and expanded metal were found rusted more or less, and also the angles and flanges of girders, showing that the paint had in many cases been rubbed off, or had not been coated after fixing. Considerable care and supervision is necessary in seeing that the specified coats are applied. The splice plates of columns are often found to have rusted behind, caused by scraping, or the paint has been rubbed off, so with heads of rivets, which are often rusted before the flanges and webs. All machined surfaces, pinholes, riveted work should be painted or coated with pure white lead and tallow, and after erection another coat of paint is necessary, or boiled oil should be worked into all joints.

The subscriptions to the fund for the erection of the Queen Victoria Memorial in London have reached the sum of £230,000. The architect, Mr. Aston Webb, and Mr. Thomas Brock, the sculptor, are proceeding with the work.

Sir Robert Giffen, in a paper recently presented to the British Association, showed that £223,000,000, or 16 per cent. of the total annual expenditure of the British people is spent for housing, including furniture, coal, gas and water. The speaker "considered the sum to be very large, and that probably in various directions, by individuals and classes, perhaps so much is spent that there is considerable economic waste; but for the mass of the people the housing arrangements are not sufficient for civilized life, or even for good health."

NEW CANADIAN EMIGRATION OFFICES.

The remarkable growth of emigration from Great Britain to Canada has necessitated the erection by the Dominion Government of large new offices in London, England. These new offices, which were opened in April, are located at Charing Cross, in the centre of the Metropolis. They comprise a very imposing block of buildings of commanding appearance, and should proqide adequate accommodation for the purpose for which they have been erected for many years to come.

The accompanying illustration shows a portion of the interior of the ground floor. It is partitioned off for various departments. The office of Mr. T.R. Preston, the Canadian Commissioner of Emigration, is on the ground floor. All the fittings are of Canadian wood, comprising bird's-eye maple, cherry, ash, and oak, the fittings having been mainly supplied by the Office Specialty Company, of Toronto, and the Canadian Office and School Furniture Company, of Preston. All the offices are admirably arranged to meet the work of this department, which now comprises quite a considerable staff.

New Canadian Emigration Offices, London, England.

THE BUILDING TRADE AND MR. CHAMBERLAIN'S PROPOSALS.

The building trade of this country is very directly concerned with Mr. Chamberlain's fiscal proposals, says the London Builders' Record. We are largely dependent on other countries for certain building materials. Brick and stone are home products and may be set on one side; but wood, cement, joinery, rolled iron joists, glass and numerous other goods are imported in great quantities from countries which would be penalized by Mr. Chamberlain's tariffs. A few weeks ago we published some figures showing how the McKinley tariff of 40 per cent. on manufactured granite goods had affected the Aberdeen trade, the total value of granite shipped from that port to the United States having dropped from £112,382 in 1891 to £19,710 in 1902: so that the more favourable tariffs prevalent with our colonies (Canada being only 20 per cent. and Africa 10 per cent.) has led granite merchants to very seriously consider the Colonial Secretary's scheme. Then as regards cement. During recent years the English market has been invaded with foreign cements: in 1901, more than 220,000 tons came from Germany, Belgium and the United States, as compared with 105,000 tons in 1900. America is likely to be a great competitor for the cement market of Canada; the latter country having largely deserted us of late in favour of the enterprising nation next her boundaries. In this latter connection account should also be taken of the rapid growth of cement manufacturing in Canada, the Canadian product having largely displaced the imported article.

THE COLOURS OF STAINED GLASS.

Mr. Walter Rosenhain points out, says the Builders' Record, that the loss of the secret to produce the tints of old stained glass is not indeed a loss, for the secret was never our's, but was always one of Nature's. Glass changes its colour under the influence of light, as anyone may perceive who will glance upward at an old railway terminus roof and notice how some of the panes have changed from their original greenish tinge to yellow or even pink. A large number of experiments have been made on this subject, and Professor Gaffield has carried out a series of tes's, lasting in some instances over thirteen years. He found changes of colour, in what may be termed "white" glasses, as follows:—From white to light yellow, light green to yellowish green, brown and greenish yellow to various tints of purple, light green to light blue, and in some cases merely a deepening of the original tint. In the majority of coloured glasses he found little alteration except in violet and brown tints. Nevertheless, when ancient coloured glass is removed from its setting it is often found that portions of the glass which have been protected from the light are of a different tint from those portions which have been freely exposed. There can be little doubt, therefore, that we do not now see ancient glass windows with the colours they originally possessed. The change of colour is probably due to a change in the state of oxidization of the manganese and iron present in the glass. Professor Currie recently showed that the rays from radium have a powerful and ready effect in changing the colours of certain glasses.

—THE—

CANADIAN ARCHITECT AND BUILDER

A Monthly Journal of Modern Constructive Methods,

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD WEDNESDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBER DECORATORS, BUILDERS, CONTRACTORS, MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

The C. H. MORTIMER PUBLISHING CO, of Toronto, Limited.
Publishers,
Confederation Life Building, - TORONTO, CANADA.
Telephone Main, 2362.

Branch Offices:
IMPERIAL LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.
22 GREAT ST. HELEN'S, LONDON, E.C.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITORIAL ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1903.

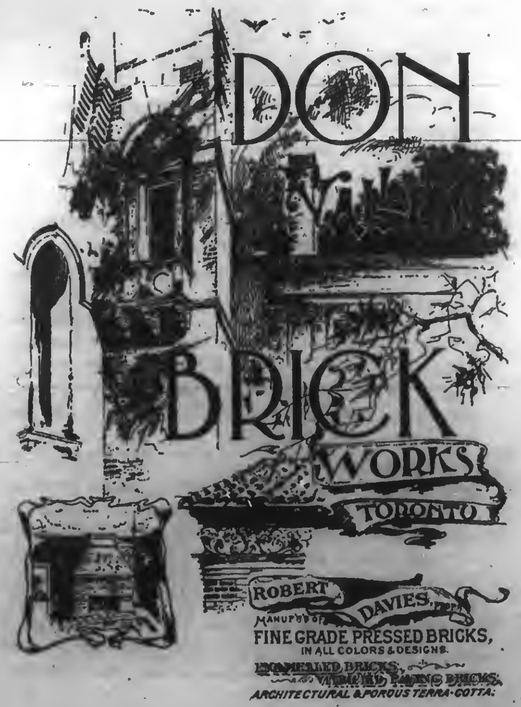
NOTES.

The method has been adopted in the United States in the case of certain classes of difficult undertakings of building with profits in the form of a commission on labor and materials. A firm of New York contractors who agreed to erect a large stone building at the actual cost of materials and labor plus 8 per cent. commission, binding themselves to the employer that the total cost including their commission and architects' fees should not exceed 20 cents per foot, are now bringing suit in the courts to determine a dispute as to what is due them.



LEGAL

In the action for damages brought by the Metallic Rooling Co., of Toronto, against Local Union No. 30, of the Almalgamated Sheet Metal Workers' International Association, Mr. Justice McMahon has decided that the officers of the local union are properly qualified to represent the other members of the local union, under rule 200. "That rule gives no power to order that the officers of the local union shall represent the other persons constituting the association, which is a foreign body, having its headquarters at Kansas, and under whose jurisdiction the whole of the local unions in the United States and Canada are placed." Order made that the individual defendants shall represent the other members of the local union. Costs in the cause.

Curiously enough the British Workmen's Compensation Acts which are mainly concerned with accidents to workmen, do not contain a definition of the word "Accident". A recent decision of English courts, however, gives us the legal interpretation placed upon it by the courts. A case which turned on the meaning of the word (Fenton v. Thorley & Co., Ltd.) was decided recently in the British House of Lords. Owing to some defect in a machine, a workman was injured in endeavoring to make it act. The County Court judge held there was no accident arising out of and in the course of the employment. The same view was taken in the Court of Appeal. Lord Macnaghten objected to the belief which prevailed in the Courts that there must be something fortuitous in the circumstances in order to constitute an accident. A workman acted stupidly and was injured, and unless serious and wilful misconduct could be proved he obtained compensation. Another did his very best, acted with energy and thoughtfulness: he was declared to be outside the Act, as the fortuitous element was wanting. His lordship considered the word "accident" should be interpreted in the ordinary sense. In conclusion he moved that the decision of the Court of Appeal and of the County Court judge be reversed, with costs in both Courts, and that the action be remitted to the County Court with a direction to the judge to ascertain the amount of compensation to which the appellant is entitled.

The general practice in building, that if the employer is dissatisfied with the manner in which a contractor is carrying out his work he may, after due warning, engage any other person to complete the work, has been once more upheld in Scotland. In a case lately heard, says the Builders' Reporter, the plaintiff was accepted for a contract to carry out the joinery work in three blocks of buildings. He claimed £210 19s. for work in connection with the buildings, and also £500 as damages for breach of contract in respect of the architect having taken the contract out of his hands after the roofs of the buildings were on. The owner of the buildings, who was the defendant, stated that he was willing to pay whatever sum the architect might certify to be due. The position he took up with regard to the claim of damages was that the architect had power under the contract to take the contract out of the contractor's hands, and that he was justified in doing this owing to his dissatisfaction with the progress made with the work. The claim for work done was referred to an independent architect, who fixed the amount at £187 19s ½d. This sum was awarded to the contractor. The claim of £500 damages for cancelling the contract was dealt with at some length. The Sheriff-Judge, in his decision, found that the plaintiff was not entitled to damages for the following reasons;—That he did not fulfil the terms of the contract, but that at several stages of the work, in consequence of his materials not being forward, he caused serious delay and inconvenience to the other tradesmen, especially to the mason, and retarded the progress of the work. After several delays caused by the pursuer, it became apparent that he was not carrying on his work in such a way as was compatible with its being finished at the earliest possible date; that the defendant's architect, after reasonable warning, wrote to the plaintiff intimating that the contract was taken out of his hands; that the architect was justified in terminating the contract. The case exemplifies the disadvantages of splitting up the contract, for the speed of progress is thereby regulated by the slowest. For instance, the mason had to take his men for three weeks from the walls owing to the absence of joists. The delay about the joists was caused to a large extent by the plaintiff supplying joisting of an inferior quality to that which was specified. According to Mr. Morton, the wood merchant, he ordered joisting of a grade inferior to that specified, and at a price at which the specified quality could not be supplied. There was a similar delay when the walls were ready for the second-floor joists. The ceiling joists were not even ordered from the timber merchant at the stage when it was usual to lay them. The evidence was overwhelmingly against the plaintiff, and the decision could not do otherwise but reflect that fact.

The builders of high chimneys in Germany are now using a mortar composed of a mixture of cement, lime and sand (in the proportions of 1, 2 and 6) for the upper portion of the chimney stack, where the gaseous products of combustion of the fuel are comparatively cool; while for the lower portions of the stack the proportions are 1, 2½ and 8. If the lime is hydraulic the proportion of the cement may be reduced; but if the sand is very sharp the proportion of cement must be increased. For the cap of a tall chimney stack the proportions of the ingredients of the mortar may be altered with economy and advantage. In German practice the mortar is composed of cement, lime and sand; in the proportions of 1, 1 and 4. Mortar made of cement and sand alone is not at all suitable for tall chimney work, because it does not resist the action of heat well and is attacked by carbon dioxide, of which there is always a large quantity present in the fine gases; this is especially the case in the presence of moisture, and, of course, steam is always present in the gases found in a smoking chimney.

STANDARDIZING OF BRICKS.

At a conference representing the Royal Institute of British Architects, the Institution of Civil Engineers and the Institute of Clayworkers held in London on June 19th last, approval was given to the proposal that in future bricks should be made to a standard size as follows :

1. The length of the brick should be double the width, plus the thickness of one vertical joint.

2. Brickwork should measure four courses of bricks and four joints to a foot.

Joints should be ¾ in. thick and an extra 1/16th, making 5/16ths for the bed joints to cover irregularities in the bricks. This gives a standard length of 9¾ in. centre to centre of joints.

The bricks to be measured in the following manner :

A. Eight stretchers laid square end and splay end in contact in a straight line to measure 72 in.

B. Eight headers laid side by side, frog upwards, in a straight line to measure 35 in.

C. Eight bricks, the first brick frog downwards and then alternately frog to frog and back to back, to measure 21½ in.

A margin of 1 in. less will be allowed as to A, and ½ in. less as to B and C.

This is to apply to all classes of walling bricks, both machine and hand made.

NOTES.

White walls are the latest mania of the art decorator, says the Daily Graphic. A good many smart houses are being done with walls of white Lincrusta all the way up—the hall, staircase, and rooms all to match. The friezes and dados of the library and dining-rooms are sometimes made of old oak, and the white walls make an excellent background for oak furniture.

The Toronto Chapter of the Ontario Association of Architects and the Toronto Engineers' Club, have decided to hold every Monday joint luncheons. Formerly the members of each society met separately for this purpose. The new arrangement will no doubt promote acquaintance and sociability and enhance the general interest and success of these gatherings.

There is no branch of masonry construction which has experienced greater advances within the past few years, says Engineering Record, than Portland cement concrete. Applications for it are constantly being found in more or less new conditions, either with or without steel reinforcement. Some who formerly were apprehensive in regard to the weathering properties of its exposed surfaces have found that it may be made durable even under the most trying exposure. The best methods of its preparation have been found to make it so nearly watertight that it may easily be given that highly desirable quality for all practical purposes.

A writer in the "Yorkshire Post" observes that it is a curious fact, and one which emphasizes all the rest, that the most artistic of modern houses are those of the very wealthy and the very poor. The rich are building their own; the poor in a few favored places, are having their's built for them, and in their different ways they are the nearest approach we have to model homes. Between these extremes comes the great wilful and inartistic middle-class, for whom there is being provided on all hands architecture that would be laughable where it not so sad. Scores of examples of it may be seen in the suburbs of any growing town—painfully modern villas of every possible degree of ugliness and inadaptability. In general they are supposed to be imitations of various "styles" of architecture, but here and there may be found a case of absolutely original eccentricity.

With the object of forming a great dam to provide a water supply for the city of San Francisco, a great section of mountain was recently torn off by 10,000 lbs. of powder, lifted several feet straight up, and then pushed bodily forward 40 ft. or 50 ft., then falling 125 ft. into the desired position. On the surface and in places through the mountain side were placed big deposits of giant powder for the purpose of shattering the mass and lifting it up. According to plans the powder when it exploded would hurl the mass straight forward, making a bridge of granite across the gorge and blocking the stream. The plans were carried out with the greatest care, and with a successful result. When the dust cleared away, it was found that the powder had dislodged a mass of rock 400 ft. up and down stream and an average of 60 ft. in height, completely bridging the canyon. The engineers estimated that the amount dislodged weighed about 150,000 tons.

A City Architect For Toronto.

Mr. Robert McCallum, for many years on the engineering staff of the Department of Public Works of Ontario, has been appointed city architect of Toronto. Apart from the peculiarity of having a civil engineer as city architect, Mr. McCallum's knowledge of constructional methods and materials should qualify him to pass upon the structural fitness of proposed new buildings, and to decide whether in structures new or old the construction is safe. We presume it is not the intention to place the designing of important city buildings in his hands. If so, why that is a matter requiring entirely different qualifications. The completion and adoption of the proposed new building by-law should follow as a natural sequence the appointment of a city architect. Mr. McCallum should lose no time in urging the City Council to deal with this important matter.

Sand for Building.

A company who are carrying out some dredging contracts in the neighborhood of Toronto, are sending out circulars to the architects of that city offering for sale what they call "water washed sand" for building purposes. A higher price is asked for this material with the high sounding title on the ground that the "water-washing" (whatever that may mean) ensures a higher standard of quality. Whether such is the fact or not, we cannot but admire the ingenuity exercised in seeking to find a profitable outlet for what would ordinarily be regarded as a valueless product. In this connection it may be mentioned that the lake sand used for building purposes in Toronto varies greatly in quality according to the location from which it is obtained. In some places on the lake shore the sand is clean and sharp, while in others it has a powdery coating which greatly lessens its value when used with lime and renders it altogether valueless if used with cement.

The New Toronto Public Library.

The City Council of Toronto have approved of a down-town site for the proposed new public library building. It has also been settled that the reference and circulating libraries shall be housed in one building. This is a wise decision. The best use will be made of Mr. Carnegie's liberal gift by concentrating the expenditure in a well designed and planned building on a site convenient to the business center of the city. If proper care is exercised the building itself will form an interesting addition to the public architecture of the city, while being most convenient of access to a majority of all classes of the citizens. The

council should follow up its first wise action in this important matter by taking steps to secure the best possible design and plan for the building. Care should be taken to prevent the commission going into the hands of "the man with a pull." The best results would probably be secured by a limited competition among Canadian architects, governed by conditions approved by the architectural associations of Ontario and Quebec.

L'Art Nouveau in Architecture.

The merits of the so-called new art for any purpose are open to question. Its employment in any form of construction seems to be a violation of the principles which are generally recognized as underlying all work of this nature. Apart perhaps from its sparing employment in decoration, it should have no place in architecture. Yet it has found its way, and indeed has become a leading characteristic of recent work of not a few of the architects of Continental Europe. The results cannot be regarded as other than deplorable. The principles of construction, of proportion and of good ornamentation are all set at defiance by architects whose fancy has been caught by the new art. It is a cause for thankfulness that the craze thus far has not taken possession of architects either in the United States or Canada. It is to be hoped that notwithstanding the influence of the French school on the architecture of the United States, it may not be considered necessary to copy the new art vagaries introduced by French and German architects. Some of the new buildings embodying these characteristics recently erected in France and Germany should serve as examples sufficiently horrible to deter architects with a reputation to make or preserve from having anything to do with this fad.

Casement Windows

The artistic effect of casement windows has always been appreciated by Canadian architects, but only within the last decade has their use been ventured upon in domestic work. The earlier generation of architects were taught that the casement window was not adapted to and should not be used in this climate. They in turn taught the doctrine to their apprentices. The latter, constituting the practitioners of to-day, have to a considerable extent departed from these teachings, and are using the casement window in house architecture with very pleasing results. It is nevertheless true, that difficulty is experienced in making this style of window weather-tight in this climate. The source of the trouble lies in the use of wooden frames which are bound to shrink. In England steel frames are used and this would no doubt overcome the difficulty here. In view of the extent to which casement windows are now being used in new houses, especially in Toronto and vicinity, where the climate in winter is moderate, there would seem to exist an opening for some enterprising manufacturer to place on the market a steel casement window frame.

Foreign Recognition of Canadian Skill.

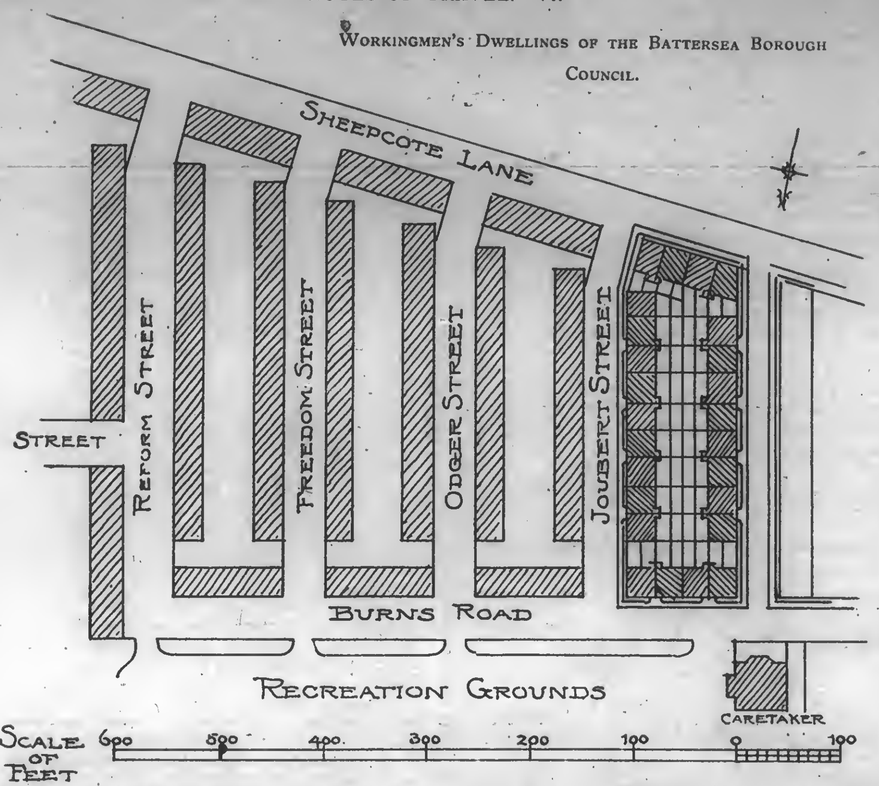
A Canadian firm of stained glass manufacturers have recently received from the United States several commissions for memorial windows. The first of these commissions came as the result of an inspection of work done in Canada, and subsequent ones because of the satisfactory manner in which the first work done in the United States was carried out. American opalescent glass was used in this work. An import duty of 20 per cent. had to be paid on the raw material, and an export duty of 45 per cent. on the manufactured article. This duty was added to the price and was paid by the purchaser. That the customer should have been willing to pay this extra price for Canadian work is highly complimentary to Canadian skill. Notwithstanding that a great deal of American ornamental glass is purchased in Canada, every obstacle was thrown in the way of the Canadian firm seeking to do business in the United States. In this connection it seems proper to refer to an occurrence which, if the facts are as stated, demands explanation by the Canadian Minister of Customs. It is said that a United States firm of ornamental glass manufacturers lately received an order amounting to about $10,000 for memorial windows to be placed in a church in Montreal, and that the duty of 30 per cent. paid on these windows was afterwards refunded by the government. If the facts are as stated, the action can only be designated as an outrage. The refund is said to have been made because it was represented that the windows were to be used for religious purposes. The tariff, however, makes no such distinction, and no official should be permitted to grant privileges outside of its provisions. Otherwise our so-called National Policy is a farce, and in its administration great injustice may be done.

Architectural Accessories.

The growth of wealth and travel is resulting in a higher appreciation by Canadians of the refinements of life. Domestic architecture especially is receiving greater attention than at any previous period during the present generation, and in consequence is showing great improvement. Architects who now aspire to be leaders in their profession must not only possess a knowledge of how best to meet the varied requirements of modern commercial and domestic life, but in addition must have the artistic faculty highly developed, so that they may be able in their designing and planning to combine beauty with utility. The fact is also becoming recognized that good architecture can only appear to best advantage when in its proper setting. Therefore, due attention must be given to architectural accessories, which term includes questions of site and proper arrangement of grounds. This phase of building to which so much thought is given in older lands is now receiving greater attention from Canadian architects and building owners. That there is yet plenty of room for improvement in this direction is evidenced by the ugly unpainted high board fences used to separate one property from another. Such fences are a serious disfigurement to many otherwise attractive houses erected in good residential localities in Toronto this year. Are these ugly fences the result of false economy on the part of owners who, after spending thousands on their buildings, spoil the effect by trying to save a few dollars on the fencing, or is there available to the architect no better method of partitioning properties? Whatever the cause, the disappearance of the unsightly board fence would be welcomed as marking another advance in architectural development.

NOTES OF TRAVEL.—VI.

Workingmen's Dwellings of the Battersea Borough Council.

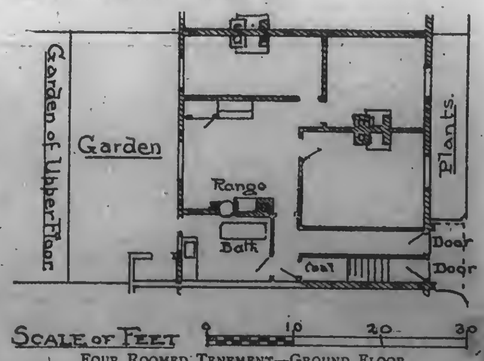


The Latchmere Estate buildings in Battersea are a good illustration of two things—workingmen's dwellings and municipal contracting. They are the work of the municipality of Battersea and occupy a portion of a piece of public ground belonging to the Borough. This land was originally let out in gardening allotments at a rental which, as it brought in only £16 a year to the municipality, must have been merely nominal. As not much good was coming of this (no doubt, under a system of gardening in a small way, the land did not improve), the idea occurred to someone that the ground might be turned to greater public advantage by building upon it dwellings suitable for working men.

Battersea is a borough in which working men are powerful. It is the constituency of Mr. John Burns, and, whether or not he conceived the idea, he was a principal promoter of the scheme and the mover of the bill in Parliament to authorize the work.

The result is evidently a financial success. The 315 dwellings, which are being erected now, are taken up as fast as they are finished and promise, when all are completed and occupied, to return an annual rental of £7000, instead of £16 as formerly. This means present work for residents of the borough; good homes for 315 families among them; and an application of the annual expenditure in rent by these families so as to reduce the poor rate of the borough to the extent of £7000 a year.

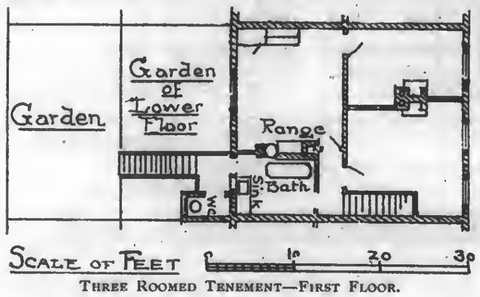
The trapezoidal piece of ground occupied by these buildings is about 800 ft. in greatest length, by 550 ft. in greatest depth. The houses are built in rows and the streets are close together, leaving only enough land in the interior of the blocks to give for each dwelling a drying-ground about 10' 6" by the width of the house. The streets are 40 ft. wide including the width of the sidewalks. In apparent width they are 4 ft. wider on each side, as the houses stand back that much to allow for the projection of the granolithic slab which protects the entrance doors. The granolithic paving of the sidewalks is carried through to the walls of the houses as a preventive of damp foundations, but the 4 ft. space is to be railed off and, it is said, filled with plants in tubs, to brighten the fronts. The pieces of ground at the back will probably be cultivated on each side of a central pathway, for Englishmen are great gardeners even in London. Something of the kind will be needed to beautify the interior of the blocks; the interior of the only block that is completed at present looks too much like a cattle market—all fences.



Four Roomed Tenement—Ground Floor.

The dwellings are in flats, but are only two floors high. Perhaps this is their most noteworthy point. It represents the teaching of experience, that if flats, of this kind, are to have anything of the self contained character of a home, they must have each a separate entrance direct from the street to the dwelling. A common entrance is apt to take its character from the worst occupant of the building; the sense of home for the best occupants, and the safety of home for their children is neutralized. The bottom idea of these flats is a separate entrance for each floor. The doors stand side by side on the front under one arch and one canopy; and the entrance ways run side by side, taking up three feet of room apiece. It is evident that in these circumstances, the number of entrances must be limited; and therefore the number of floors. The limitation of two floors is evidently going to pay sufficiently, and it is the making of the buildings from the point of view of the residents. The streets and the space between the houses inside of the block, though not wide, have an open appearance; and it is pleasanter and more convenient to live near the ground than to be cut off from it by flights of stairs.

There is also, in being only 10 feet up, safety from danger by fire—though these buildings are nearly fireproof. Their stairs are of wood, but there is a second stair from the scullery to the garden, starting from a landing of concrete.



Three Roomed Tenement—First Floor.

The exterior walls are 9″ brick; ground floor partitions which carry floor beams are 4½″ brick; other partitions are 3″ brick nogged or made of a concrete of breeze and cement, plastered with a waterproof plaster.

The lower floor is concreted on the ground; the upper floor has 5″ steel I beams, about three feet on centres, fitted in with a concrete of breeze and cement. The method is simple:—boards are pinned up tight to the underside of the beams and the concrete is filled in between the beams, flush with their tops.

It takes about 12 men to lay a floor expeditiously: 5 mixers at the door shovel the stuff into the house; it is further mixed by being passed on by 4 more men, who shovel it one to another, until it reaches the 3 layers, who ram it in between the beams one bay at a time. The wooden flooring is nailed directly to the concrete.

The roof is quarter pitch, covered with slates on battens. External openings have sills and lintels of granolithic cement, and the entrance door canopy is a granolithic slab about 6′ x 4′ supported by corbels of the same material. There is no other exterior detail. The only wood visible on the outside is that of the frames, doors and sashes. It is good solid building likely to last long and to keep neat.

All the conveniences, by the way, are supplied. For heating there is no occasion: the kitchen range supplies all the heat that is necessary for ordinary cold weather, and fireplaces are provided in all other rooms to give whatever additional heat is necessary. Hot water is supplied to the bath from the kitchen boiler, which is supplied from a tank connected by a ball-cock with the water main. The water comes from an artesian well bored to supply these buildings and, I believe, the municipal baths adjoining. The lighting is electric, and is also a municipal work. Each house is provided with a penny-in-the-slot meter. It is found to be most satisfactory for the user that he should pay as he goes, and experience in the other system seems to show that a penny meter will give enough current for a day's supply of light to a house of this kind. If not, it is not a case of sudden extinction and feeling for a slot in the dark; an automatic warning of the approach of the cut-off gives notice, in time for the insertion of a new penny while the light continues.

The cost of all this work is about sixpence a cubic foot. This price is probably rock bottom. The borough does almost everything for itself, and the Superintendent of Works is practically running a large contracting business under an undertaking to make his work both cheaper and better than any other; for there will be private contractors, ratepayers in the borough, ready at any moment to present at his head the double-barrelled proposition—"Why should we pay for work a higher price than we charge for it?"; "Why should we not have this work to do, since we can do it better?"

The manufactured woodwork all comes from the municipal factories; and can be easily undertaken by them for the rows of buildings progress in consecutive stages. Most of the other work is done on the ground and consists—besides the ordinary works of bricklaying, setting beams, roof building and slating—chiefly of operations in cement: floor laying, making sills, lintels and door protections, also slabs for partitions and paving. The breeze which is the foundation of all the works in cement comes from the municipal destructors where all refuse—garbage, ashes, and even (Oh joy!) tin cans—is burnt up together and makes a slag which is used in paving and other works. Some of it is brought to the Latchmere buildings and ground and sifted for the various works in cement; making both the rough basis of the ground floor and pavement concreting, the strong though finer aggregate of the flooring on steel beams, and the fine stuff that goes into the partitions. The sills, lintels, door-heads and pavement flags are concreted with granite dust.

Every building is put together with the same standard parts; so that the construction, though good, is economical. It is not likely that so low a cost per cubic foot can be reached by any work, as good, on a smaller scale. There is of course no paring of wages in the borough that elects John Burns. There is a 48 hour week with wages running from 10½d. to 1s. an hour according to skill.

The proof of a building is in the renting. One of these four roomed dwellings—the larger size—rents for 10 shillings ($2.42) a week. The rent is charged on the land as well as on the building, although the land cost nothing; but the London County Council, which lends the money for municipal improvements within the area it governs, required the estimate on which the loan was based to include a charge for land; valuing the whole site at £7000, which I made out to be between $8 and $9 a running foot of the frontages.

The actual value of the land to the tenants is doubled by the reservation of half the estate as an open space in connection with the buildings. Since the tenements are proving a success there is some talk of occupying this space with a second batch of buildings. Of course it would be a nice thing to have more good residences for workingmen in the borough, and to have their rent paid into the borough pocket; but to accomplish this by crowding seems an insufficient ending to an estate which lays claim, in the name of its streets, to such ideas and personalities as Freedom and Reform, Burns and Joubert.

I do not know who Ogden was, but may his memory be sufficient to preserve the land from such a catastrophe.

A reasonable compromise may perhaps be found in surrounding the space with houses. It would cut 50ft. off the ground all round, but there would be some 50 additional houses, and perhaps the place would look the neater for it, for the fronts of their own houses, in an orderly arrangement, would make a better boundary than the random backs of the neighbouring buildings.

W. A. Langton.

Entrance to New Majestic Theatre, Toronto.

THE NEW MAJESTIC THEATRE, TORONTO.

The accompanying engraving reproduced from a photograph shows the facade and main entrances of the new Majestic Theatre on Adelaide street west, Toronto, as they appeared a few days before the opening of the building for public performances. The building occupies the site of the Toronto Theatre. The destruction of that theatre by fire only a few months ago might have been expected to result in the erection in its place of a thoroughly up-to-date structure. How far this expectation has been fulfilled from the standpoint of artistic design the illustration will show. The theatrical profession is supposed to be composed of artists. Theatre buildings should therefore be artistic in design, and in many cities of the United States and Europe they stand in the front rank in this regard. The most notable example is the great opera house in Paris designed by Garnier, the principal entrance to which is shown herewith. Not only is the new theatre in Toronto not artistic, it is so conspicuously ugly as to be a positive eyesore.

On the ground of public safety also the building seems to be deserving of criticism. Notwithstanding the fate of its predecessor no attempt seems to have been made to render it even fire-resisting, not to say fireproof. Wood and plenty of it has been employed in the construction. The arch above the main entrance is a mass of wood veneered with plaster. In the event of the building being attacked by fire, we fear it would prove a veritable tinder box.

On either side of the main entrance are smaller entrances to staircases leading to the galleries. These staircases, which are steep and narrow, appear to be enclosed on one side by a plaster wall and on the other by the outer wall of the building. Doors opening off these staircases on both floors give access to and exit from the galleries. In the event of a fire or panic the occupants of the galleries might find their only exit by the staircase blocked by smoke and flame. The height, narrowness and steepness of these stairways would in such an event be likely to lead to many persons falling and being trampled to death.

In cases wherein damages have been sought for injury or loss of life occasioned by defects in public buildings, the Canadian courts have interpreted the law to mean that in the construction of such buildings every human precaution must be taken to prevent accident. It will scarcely be contended that this new theatre comes within reasonable distance of this standard.

The actual responsibility for the safety of such buildings, however, lies with the civic authorities and officials. If Toronto had a properly framed building by-law and competent officials to enforce it, it would not be possible for fire traps to be erected. The existing building regulations are in such a chaotic state and so out-of-date as to be almost useless. The only clause we have been able to find bearing on the construction

Entrance to Grand Opera House, Paris.—H. Garnier, architect.

of public buildings is the following, adopted January, 1890:

"No church, hospital, college, school, hall, theatre or other building of a like nature * * * shall be used or hereafter constructed unless the same contains such a number of doors, halls, stairs, stair railings and other means of egress of sufficient size and strength as in the opinion of the Inspector of Buildings shall afford ample facilities for free and rapid egress in case of fire, panic or other cause. No such building shall be erected or altered until the plans * * * shall be submitted to the Inspector of Buildings and certified by him as conforming to the requirements of this by-law."

It will be seen that the character of construction is not defined, but everything is left to the opinion of the Building Inspector. What that opinion is worth may be learned by an examination of the theatre building under present consideration.

There is no more important duty confronting the new city architect and the City Council than that of preparing and adopting at the earliest possible moment an up-to-date building by-law.

THE IMPROVEMENT OF THE CAPITAL.

The Ottawa Improvement Commission appointed to disburse the yearly grant of $60,000 by the Dominion Parliament for the beautifying of the city are going about their work in a wise manner, by first securing the advice of an expert as to what should be done. For this purpose the Commission engaged the services of Mr. Frederick G. Todd, landscape architect, of Montreal, whose preliminary report is before us.

Mr. Todd points out that the proposed improvements should be national in character, as befitting the capital of the nation. He properly emphasizes the wisdom of looking far enough ahead to provide for the future requirements of a city which he estimates will in fifty years have a population of 300,000. The exercise of such wise foresight will save large sums of money which would otherwise have to be spent in the future in removing obstacles out of the way. The report states that while Ottawa can never be "the Washington of the north," as some writers have predicted, because its topographical situation is entirely different, its location and surroundings are such as admit of development on an even grander scale.

As a capital city it is suggested that the parks and open spaces should be numerous with ample boulevards and parkways skirting the different waterways as well as connecting the principal parks and public buildings.

The principal suggestions are that forest reserves be secured in the Gatineau Valley and at Marsh Lake, which should contain specimens of the trees comprising the once great forests; that suburban parks be established as follows: 100 acres adjacent to Rockliffe Park, including the shores of Hemlock Lake, and east of Rockliffe Park along the river as far as the rifle range; just below Remous Rapids at the west end of the city; on both sides of the river west of Herdman's Bridge, at the south end of the city; and at the mouth of the Gatineau river extending to Pond Creek for the adjoining city of Hull.

The report suggests the location of connecting boulevards, including a drive along the bank of the Ottawa river between Rideau Hall and the Parliament Buildings, which, on account of its magnificent views would become famous the world over. This boulevard should terminate in a monumental circle which could be made to form in connection with Dufferin Bridge, a dignified approach to the Parliament Buildings. To this end Dufferin Bridge should receive proper embellishment. Emphasis is laid on the necessity for the preparation of a proper plan showing in detail how these improvements should be carried out in advance of any action being taken in that direction, also the importance, once a plan is decided upon, of allowing no departure therefrom.

C. A. AND B. STUDENTS' COMPETITION.

The publishers of THE CANADIAN ARCHITECT AND BUILDER invite architectural students in Canada to submit designs in competition for a Public Library to contain 10,000 volumes.

The Library is to be built in a small park in a country town.

The drawings required are: two elevations, one sectional view and plans of each floor. The plans, section and one elevation must be drawn in strong lines with pen and perfectly black ink on white cardboard or drawing paper. The principal elevation must be a wash drawing, the colors used being such as can be photographed. In making this drawing of principal elevation competitors are requested to bear in mind that to ensure satisfactory reproduction strong contrast in shading is necessary. It is required that the drawing of principal elevation shall also indicate the character of the surroundings and principal approach to the building.

Drawings should be made to ⅛ scale in a manner to permit of reproduction within the limits of a double page of the CANADIAN ARCHITECT AND BUILDER, i.e., 10x15 inches in size.

Competitors should state the materials proposed to be employed in construction.

Drawings for this competition should be signed with a motto only and be accompanied by a sealed envelope bearing the same motto and enclosing the full name and address of the designer and the name and address of his principal. They should be sent FLAT by post or express, charges prepaid, addressed "CANADIAN ARCHITECT AND BUILDER, Toronto, Canada—Students' Competition," and must reach this office not later than noon on Saturday, January 16th, 1904.

The members of the Educational Committee of the Toronto Chapter of the Ontario Association of Architects and the Toronto Architectural Eighteen Club have kindly consented to judge the designs submitted in this competition, and their decision will be final.

The prizes offered are: First prize, cash $15.00; second prize, cash $10.00, third prize one year's subscription to the CANADIAN ARCHITECT AND BUILDER ARCHITECTS' EDITION.

The publishers of the CANADIAN ARCHITECT AND BUILDER reserve the right to publish any of the designs submitted and to withhold the prize if in the opinion of the jury the designs should not be found worthy of the awards.

Intending competitors are requested to read carefully the conditions of competition, and to strictly comply with the same in every particular.

The Bureau of Forestry of the United States intends to resume the work of testing timber. The Bureau aims at practical results, such as the values expressing the strength and stiffness of the principal species of timber.

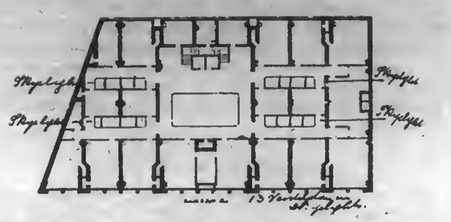
CORRESPONDENCE

VENTILATION OF OFFICE BUILDINGS.

WINNIPEG, MAN., Oct. 13, 1903.

To the Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—I see that some sanitary authority has called attention to the bad ventilatinn in some of the sky scrapers of the larger American cities, although there have been large sums spent on



PLAN OF FOURTH AND FIFTH FLOOR, MCINTYRE BLOCK, WINNIPEG, MAN.

the mechanical ventilation of same. Judging by the experience I have had with the McIntyre Block illustrated herewith, large buildings can be well ventilated at reasonable cost and without any so-called mechanical ventilation appliances, the operative charges for which are somewhat heavy to say nothing of their first cost.

The McIntyre Block has a frontage on our principal street

MCINTYRE BLOCK, WINNIPEG, MAN.

here of 173½ feet, and the sketch with plans will give a fair idea as to size. Every suite of offices has a connection to one of the numerous ventilating chimneys or shafts in the fire walls, which are shown on sketch plans. I never was in a better ventilated building (either large or small) in my life, and if desired I can detail easily provable facts that bear out my assertion that the ventilation is really good. I don't wish to advertise the McIntyre Block or to bring my name into question, but would not a discussion in your journal on this matter be both interesting and instructive to your subscribers? The general construction of the McIntyre Block, apart from the ventilating shafts, may possibly have a good deal to do with the success I speak of. Trusting the above may be of interest.

Yours truly,
WM. LITCHFIELD.

HOLLOW BUILDING BLOCK CONSTRUCTION.

New York, November 6th, 1903.

To the Editor CANADIAN ARCHITECT AND BUILDER:

SIR,—Some time during 1902, we were very much interested in an article, which appeared in your columns under the caption "Tests of strength of hollow building blocks" in which you suggested their use for outer wall construction; enumerating the advantages possessed by them for that purpose as principally: the saving of weight, of great importance, especially where the material must be sent great distance; this saving of weight of further importance as it lessens the load on the foundations;—the air spaces insure a drier wall and greater rapidity in laying.

Your article closes "It would therefore appear in general that hollow blocks should furnish a wall amply strong for the circumstances under which they are commonly used."

It might interest your readers to learn that the idea is no longer in the experimental stage, but has proven to be highly practical: and the advantages you suggested as being possessed by the hollow blocks for wall building, fully demonstrated in actual operations.

Making the blocks of hard burnt terra cotta, 4"x8"x12" and weighing 16 lbs. each, by the addition of band-iron between the courses, we have constructed walls 350 feet x 200 feet and 24 feet 6 inches high, of a tank house for the American Smelting & Refining Co. at Perth-Amboy only 4" thick, which were computed by their engineers as being equal in solidity to walls of common brick 12" thick; while saving in weight some 800 tons, a matter as you state of the greatest importance where the material must be sent any distance; and a further saving of fully 33 1-3 % in cost, taking price for common brick as $5.75 per thousand, a very low estimate.

We are under contracts with the Barber Asphalt Paving Co. to erect several buildings with this wall, for their new plant at Maurer, N. J., some of which being completed, we are enabled

to give in greater detail the actual cost per square yard.

Cost of a "Phœnix" wall 4 inches thick and 15 feet high.

MATERIALS.

One 6-inch upright I-beam, for every 15 feet of wall (one beam to every 25 sq. yards of wall) weighing 14¾ lbs. per foot ; 227¼ lbs. for 25 sq. yards, or 8.84 lbs. per sq. yard at $2.65 per 100 lbs.	$ 0.24
Band-iron (1-16 in. x 1 in. wide) laid on every course of blocks ; 350 feet of iron to every 25 sq. yards, or 14 feet per sq. yard weighing about 1¼ lbs. at $3.20 per 100 lbs.	.04
Portland cement for every 150 feet 1 barrel at. $ 2.50	
Sand, ½ cubic yard, $1.25 .63	
Cost per sq. yard	.19
"Phœnix" blocks (4x8x12 ins.) 9 sq. feet at 12 cts.	1.08
	$1.55

LABOR.

A mason will easily lay in 8 hours—150 sq. feet of these blocks, at 65 cents per hour $	5.20
Helper, 8 hours at 37½ cents per hour	3.00
Total for 150 sq. feet $	8.20
Cost per sq. yard for labor	.50
Cost per sq. yard of "Phœnix" wall $	2.05

The estimated weight of a wall of " Phœnix" construction (4x8x12) 4 in. thick, and one of common brick 12 in. thick, say 200 feet long by 15 feet high gives :—

4500 "Phœnix" blocks at 16 lbs. each	72,000 lbs.
I-beams	2,780 "
Band-iron	700 "
Total	75,480 "

The same wall of common brick 12" thick, would contain 3,000 cubic feet, which even at the exceedingly low estimate of 100 lbs. per cubic foot would give 300,000 lbs. for the weight of wall, including the mortar.

Yours very truly,
HENRY MAURER & SON.

EFFECTS OF CINDER CONCRETE ON IRON AND STEEL.

To the Editor, CANADIAN ARCHITECT AND BUILDER.

MONTREAL, Oct. 18, 1903.

SIR,—Enclosed please find copy of a photograph recently taken of some work done about ten years ago and which is a good illustration of what cinder concrete will do to iron and steel after a certain length of time.

This occurred in a building to which an extension is now being built, and cinder concrete (fortunately) was only used under a fireplace situated exactly where this wall was taken down to continue the extension now in course of construction. The place is still visible to any one who wishes to verify the facts.

Yours truly,
N. T. GAGNON,
Secretary Montreal Terra Cotta Lumber Co.

BUILDING CONDITIONS IN HAMILTON.

The following extract from a letter received from a Hamilton architect shows the unusual activity in building operations prevailing in that city this year: "There is more work on here than there are men to do it and the result is that work is dragging along very slowly, causing much complaint from clients and leading architects. Of late, on alteration work, I have not called for tenders, simply going to a few reliable men and getting the promise of the required workmen and then letting them go on with the work."

PRESERVING STONEWORK.

In a recent address at the Royal Academy in London Professor Church gave some valuable information regarding the use of baryta water for the preservation of frescoes and stonework against injurious atmospheric influences. Baryta water can be used with safety when twenty times stronger than lime water, and the sulphuric acid in London's atmosphere, though it destroys the lime in a fresco, forms in combination with baryta an insoluble and practically indestructible substance which preserves from harm the colors of the painting. Professor Church said that he had been using baryta with success in the Chapter House at Westminster, where the thirteenth-century stone-carving has practically been converted into gypsum by the action of the atmosphere. So bad was the state of this carving when Professor Church commenced his treatment that when touched portions would adhere to the fingers, and it was liable to be damaged even by the slightest touch with a feather brush. He thought, however, that the application of the baryta water had preserved the carvings from further deterioration.

NOTES.

The Royal Commission on monuments of Belgium, constituted in 1835, is charged with the preservation of ancient buildings. The Commission may schedule any building or monument, and the scheduled building cannot be touched without the consent of the Commission, even if it is in private ownership. In Belgium, as in France and Denmark, grants of public money are given for the purchase and preservation of ancient monuments, and the Belgian municipalities are very zealous in the same direction. In Bruges, we understand, the facades of all the houses belong to the municipality, so that their preservation is secured, and also congruity in the case of new buildings. No object of art may legally be alienated or removed from a Belgian church.

BY THE WAY.

The British people seem to have imbibed the craze for large exhibitions which has prevailed in the United States since the time of the World's Fair held in Chicago. It is now announced that an "International Exhibition" will be held in Manchester in 1905. I sympathize with the view expressed by some English journals, that these exhibitions have been overdone and that people have become tired of them. The term "international" as applied to most of them is a misnomer, as they are distinctly local in character.

× × ×

The New York courts have granted an injunction restraining the Allied Arts Company and the Tiffany Company from making any changes in the mural decorations painted for the King Edward Hotel, Toronto, by Wm. D. L. Dodge, a New York artist. It is understood that by direction of the architect a Canadian artist is now engaged in making alterations to these paintings. The opinion prevails here that the jurisdiction of the New York courts does not extend to Canada and cannot affect Canadian artists. With regard to this the architect is doubtless acting under legal advice.

× × ×

On one of the leading business thoroughfares of Chicago a crowd assembles every day, opposite a new sky scraper now in process of construction. Apart from the general interest excited by modern methods of placing materials in position at so great a height, the special object of curiosity is a man at a forge who heats the nuts used in rivetting together the steel framework. This man takes the red hot nuts out of the forge with a pair of tongs, and with a dextrous flip throws them up a couple of stories where they are caught by another workman stationed with a receptacle to receive them. So skilfully are the nuts thrown that the receiver has only to reach out a foot or two on either side to catch them. The swift passing through the air of the blazing nuts, like shooting stars, naturally attracts much attention from passers-by.

× × ×

The results of the attempt which has been made in New York to provide suitable accommodation for the poorer classes, is most encouraging and should stimulate action along similar lines in Toronto. Seven years ago the City and Suburban Homes Company was formed backed by a number of philanthropic capitalists. This company have built a number of carefully planned tenements for the wage earning classes. They have as tenants 360 separate families. They have issued capital stock to the amount of $1,707,250 and estimate the present value of their assets at $3,000,000. After declaring a dividend of 4 per cent. they have in hand a large sum as a sinking fund. The company's report to its shareholders shows that but small loss has been sustained from apartments becoming vacant, and that the unrecoverable arrears of rents amount to but $248.

× × ×

The lines are being very finely drawn between the various unions connected with the building trades. A short time ago a strike occurred on the King Edward Hotel, Toronto, arising out of a dispute between the plumbers and the electric wiremen as to who should put the electric wires though the ducts. More recently the contractors for a new warehouse building, in order to avoid a strike, were obliged to discharge two stonemasons who had been engaged in putting in position what is known as Roman stone, an artificial stone composed largely of cement. The bricklayers contended that this material was being substituted for terra cotta, that the latter material had always been put in place by bricklayers, and hence that to the bricklayers should belong the work of setting the new material. Rather round about reasoning this, but the kind of thing that the modern contractor has to put up with.

ARCHITECTURAL CLASSES IN TORONTO.

The joint committee of the Ontario Association of Architects, and the Toronto Architectural Eighteen Club has now completed arrangements for the classes to be held during the coming winter. On Wednesday, the 18th November, there will be resumed the class in design held in the rooms of the School of Art and Design, 165 King Street West. In this class there will be senior and junior sections, open to all draughtsmen and students, and those intending to join are reminded that it is most important to be present on the opening night as the problem will then be stated and preliminary instructions given. The services of an ex-pupil have been secured as instructor on behalf of the junior students while the work of the seniors is reviewed by the critics on three evenings of each week.

The mathematical classes conducted by Mr. H. A. Harkness, B.A., have already been started in the rooms of the O. A. A., 96 King Street West, and are well attended. On Monday evening, statics and strength of materials are taken up by the senior students and on Friday evenings, geometry, algebra and trigonometry by the juniors.

A fee of five dollars has been fixed covering tuition in either or both these courses and all students are invited to join. It is gratifying to those in charge to note the interest that has already been displayed and much good should be accomplished by this season's work.

METHOD OF DRYING OUT DAMP WALLS.

A writer in "L'Industrie" gives the following as a method which he has proved to be successful for drying out damp walls and humid surfaces :—Dissolve 5 lbs. of pure olein in 5 lbs. of benzine, and coat the damp surfaces with the mixture. This solution of oleic acid, owing to its great fluidity and the capillarity of the mortar, sinks deeply into the latter, and together with the hydrated lime in the mortar produces a formation of greasy lime which constitutes a waterproof coat. The proportions of the mixture can, of course, be modified according to circumstances; and, instead of benzine, other solvents of the nature of ether and benzol may be utilized. A variation of this method is the employment of other fatty or resinous acids instead of olein. The resinous acids form with the lime hydrate a resinate of lime which has the same waterproof properties as fat lime. Damp or newly-built walls thus coated may, after almost instantaneous evaporation of the liquid, be papered or painted. As in the case of walls in cellars or tunnels, this process can be also employed successfully to coat cement, terrazzo or mosaic work.

THE STYLES OF ARCHITECTURE AND STYLE IN ARCHITECTURE.

By Prof. Percy E. Nobbs.

Note By The Author:—These three short papers (1) Drawing and Architecture; (2) The Styles of Architecture; (3) Material and Design; are intended as an introduction to the study of Architecture for students assumed to possess no knowledge of the subject, and the themes are treated with regard to their bearing on study only. They were delivered at McGill University this September.

Having reached our second year as students of Applied Science at this most scientific of universities it is to be assumed that we all realize the mighty strides by which empirical knowledge has advanced during the last century and we have possibly imbibed the idea that the ancients have very little to teach us. That is a frequent effect on the mind of scientific pursuits and is one of the deplorable results of "much learning" in certain subjects. Before going a step further towards the study of art it is necessary to disabuse our minds of this prevailing modern spirit of self conceit. True we are immeasurably ahead of even our grandparents in all that concerns science but how do we stand towards the men of old time in art? Knowledge for its own sake or more often for the sake of the material power it carries with it does not minister to the sum total of humanity's requirements—a little sentiment still exists, thank Heaven! and its natural manifestation in art must still go on, though it has been nearly crowded out of our life by more material activities.

When we look back a few centuries whatever the condition of mankind might be in material power, in art we find he had attained a level to which the best of us to-day do not seriously attempt to aspire. Our best is puny stuff beside their best but that is no reason for sluggish contentment with our medium qualities.

Life generally in civilized countries was surrounded with objects of real beauty up to the beginning of the great and glorious XIX century, and in the early years of Queen Victoria's reign, the reign of ugliness in all things made by men, especially Englishmen, reached its height or rather its greatest depth. The fact that things generally were well designed in days of yore is sufficiently attested by the "craze" among cultivated persons for old furniture, old china, old plate, old anything.—Collectors are very prone to admire things merely because they are old and not infrequently understand no other standard of excellence. Still the contention that old things were generally beautifully designed and that people are again beginning to appreciate beauty in the surroundings of life is amply attested by the prices and profits of "the old curiosity shop."

Now if we go back not two hundred but two thousand years and more we find in Greece a skill and power in all the arts which no time or people has surpassed nor even equalled perhaps. The superlative excellence of the Hellens in their artistic activities (and in many more besides) has instituted a standard of perfection which, if never again reached, has at least inspired men to high attainment ever since and has directly influenced about half the artistic output of the civilization of which we are the heirs. We need only go as far as Notre Dame street for a striking case in point. The great hall of the Bank of Montreal could never have been conceived in its present shape had not the glorious Greek tradition been handed down through the centuries. In it we find the Greek spirit manifesting itself through the luxuriant American mind of to-day.

Perhaps enough has been said to convince us all that we are about to study a subject in which the men of old time are our masters, so that the fact is accepted provisionally just now before we touch on the styles of architecture that is all that is necessary. The whole proof will take a session, nay a lifetime of study and then not all be told.

A word before we touch upon the styles. This is controversial matter! The battle of the styles has raged well nigh a hundred years in England and the disintegrated state of English architecture is the result of the blows that have been dealt.

There is still a prevailing idea among such members of the public as take the trouble to have an idea at all, and among a great many architects, that architecture is a cut and dry exact science, having for its object, knowledge of certain ancient fashions of building with a view to their reproduction to-day when asked for. These fashions are "the styles" and criticism is supposed to be restricted to the question of how faithfully the fashion professed has been followed. The majority of people we meet imagine that a client who admires Francois I. buildings, can get from an architect for a certain pecuniary consideration a Francois I. design for a house, and that the house so prescribed will not only have the beautiful quality of Early French Renaissance work, but that it will be an example and should be called by that name. Or a client may select Greek Doric and order accordingly.

Now this heresy has flourished more among the English than with any other people, and "the battle of the styles" above referred to, has consisted in reviving about 50 different "styles," every architect of note bringing new battalions of ancient details to the war. However unsettling this struggle as far as national traditions are concerned, signs are not wanting that peace is in sight. The survival of the fittest is a law as true in art squabbles as in animal life.

It is an idle inquiry, whether in a building roofed in last year which bears a resemblance to many other buildings built when George II. reigned, (and manifested his "distaste for art and poetry,") has all its details and accessories done in the way the said monarch's subjects habitually did them or not. If the building was roofed in last year it must be Edwardian. No man is responsible for the date of his birth, far less a building.

We as students must study the styles in vogue since history began for a great many reasons, which we only fully appreciate after we have been at it some time. We must also use the words bandied about in common currency, and when we speak of a modern building as Bazantine, to distinguish it from another which we designate as Greek, we must bear in mind that these are superficial differences, and both are properly XX Century Canadian, and will be so described by the students of the XXXV. century, let us say, if steel construction proves as good as it's designers hope.

As Europeans in civilization, we are concerned only with two great kinds of architecture, Gothic and Classic. Saracenic and Indian are the manifestions of quite different branches of the human family. In each we shall find gradual developments leading at particular periods of great activity or special influences to the production of quantities of work of one character, usually confined to a geograpical area and a short period. By the styles we mean such types of work.

"What is the difference between Gothic and Classic?" a new arrival in a big London office once asked of an elder brother who had been there many years. "The one has cusps, the other hasn't," was the reply. The full humor of that innocent reply will, I hope, be manifest to us all before very long. Modern Gothic and Classic is apt as in that office to be a mere matter of detail; but in our studies we shall find that real live Gothic and Classic are distinguished by fundamental principles of design, deeper even than their differences of construction.

I once heard a lecturer on art, I cannot remember who define our work as a matter of arrangement. "All art, he said, is just arrangement." Suppose for instance, on leaving home, a man dines at a restaurant with a friend and decides to drink a lady's health in the best he can afford. "Waiter! Wine list, No. 730, whole one." There is no art either in doing it so, or relating it so. But how does Burns describe this very thing. "Gae bring to me a pint of wine, and fill it in a silver tassie, that I may drink afore I gae a service to my bonnie lassie."

Just so in Architecture it is merely a question of arrangement. The things we arrange are the common things of life, the windows, the doors, the chimneys, the church seatings the cathedral spires. What then are the styles? We must remember that there is an analogy between all the arts and it is very difficult to talk about any one except in terms of the others, so if we look at poetry, the greatest of all arts, we may find help. The poet also deals in plain ideas and by arrangement of them welds the mighty thoughts, or fashions "jewels six words long." But there is more; there is his metre which helps out the ideas (if he is worth a penny a line)—which holds the whole together in a form—metres as old as the hills; Why should he try invent new ones? Metres which change by degrees through the themes—the feelings that tune to. The styles are our metres—our grand old traditional and rythmic types of construction, learned from one nation by another even as the metres were, and always tuned to that nation's temperament before being passed on. The analogy is complete. Now just as some metres were made by no one in particular, but simply grew while others and these not always the best, were deliberately evolved by single genuises, so in our styles. Among the architects of the late Renaissance in Italy there flourished one Palladio of Vicenza, a mighty genius whose opportunities were not quite worthy of him. He gave to the classic forms so studied a refinement along with a dignified and large serenity, that his work became distinguished from that of all the others. He died and left a book. That book of drawings became the standard of taste in English work for nearly a century. The metre he evolved was not taken up elsewhere to any great extent.

In poetry every master uses his metre in his own especial way and it does not require a very deep knowledge of English verse to spot Shakespeare from others using a blank verse of 5 iambic feet. In architecture too every man puts something of himself into his work (even when most studiously imitating some forgotten master). This is style in the real true personal living sense. "Le style c'est l'homme" is a glorious old adage, and that most versatile theorizer on all that pertains to our trade, M. Viollet le Duc is never so happy as when dealing with this aspect of style.

No work of art was ever produced without this kind of style—it is if not the chief quality by which a work of art is to be judged at least a quality whose absence in an object is incompatible with that object being a work of art at all. Style in this sense is that stamp of individuality that makes a building partake at once of the soul of the man who conceived it and the people that reared it. English, French and Italian work is characterized by broad differences of national temperament, independent of the century or the outside influences. This is the main reason for the growth of the diverse styles in spite of the fact that the architects of most periods have gone back to former times for inspiration. The Romans copied the Greeks whose superior artistic powers they always acknowledged. The XV Century Italians deliberately imitated the Romans. The English later on followed the Italians and to-day some of us at least are trying to hold onto those same English XVII Century traditions. Yet Greek, Roman, Italian, English and Modern Classic work all have wide enough differences to entitle them to be named as separate styles and nothing will sharpen our senses to the beauties of what has been done or fit us better to solve our own modern problems with an absence of utter ugliness than the comparative study of the styles both in the narrow popular sense of mere metres or forms and in the grand sense of all that makes for character in work.

HOW TO MAKE A LAWN.

The lawns in the 69 acres comprising the agricultural section of the Louisiana Purchase Exhibition at St. Louis are exhibits, and they have been as carefully planned as any of the other show spots in the outdoor section. Already they are beautiful and each day adds to their attractiveness.

The conditions under which these lawns have attained so great a degree of perfection establish beyond question the fact that splendid lawns may be grown under the most discouraging conditions. All along the east side of the great Palace of Agriculture a few months ago was a mass of yellow, sticky clay. A ravine, 17 feet deep, was filled with clay brought from the top of a neighboring hill. This was smoothed, plowed and harrowed and a top dressing of good soil, nearly a foot thick, was spread over the clay. This was worked, pulverized and prepared for the seed.

The seed selected was blue grass and rye grass, mixed in equal parts. The rye grass was first in evidence, but it has done the work that was required of it and has passed away. The visitor will never know it existed, unless he makes inquiries and learns that the blue grass is indebted for much of its beauty to its less known brother, the rye grass. The rye grass peeps up in six or seven days and is a nurse crop for the blue grass. It grows taller and shields the blue grass from the sun. It is perennial, and as it is not permitted to go to seed on a well regulated lawn it dies out and leaves the blue grass alone on the field.

One can tell on an October morning in St. Louis why it is called "blue grass." Walk over the lawn early in the morning before the dew has disappeared. The rye grass is the taller, and with its spears covered with dew it has a vivid green color. The blue grass spears are nearer the ground and in the coating of dew each spear takes on a light blue, but an unmistakably blue color. The blue grass is exclusive, and wherever it takes a stand all weeds and other common grasses are crowded out.

But there are things about planting that Mr. Hadkinson, superintendent of outdoor planting, knew and did that had much to do with the success of the lawns. After getting the ground into proper trim the seed was sown, broadcast by hand, one pound to each one hundred square feet. The seed was covered with what he calls a "choppy" motion. A gardener goes over the lawn with a rake, and instead of raking and rubbing the seed in, he swings it slightly and allows the teeth to enter the soil about an inch. When the rake is lifted the soil is turned under for about half an inch. The pulverized soil must be treated to fasten the seed in the ground. On the comparatively level places, a heavy roller is used. On the terraces, and some of the terraces incline at an angle as great as 30 degrees, a "pounder" is used. This is a board a foot wide and a foot and a half long, fastened to a handle with blocks added until it weighs about 15 pounds. The surface is "tamped" with this.

When the earth is smoothed the final work is done. All summer long a great pile of stable manure had lain in a neglected heap in front of the garden. It was thoroughly decomposed. This was run through a soil pulverizer and after being granulated was sprinkled over the ground. The covering is slight, but is all that is needed. It keeps the sun from baking the soil and causes it to retain the moisture. No other fertilizer is used. Having done this, Mr. Hadkinson waited, and nature is doing the rest.

There is one pest that has demolished many a beautiful lawn, and the World's Fair landscape gardeners had a short bout with it before they succeeded in overcoming it. This pest is the mole. These little fellows with wonderfully powerful fore paws, and soft and glossy fur, burrow a few inches under the surface of the ground and raise ridges in the lawn. The moles feed on the earthworms and harm the roots of the grass only incidentally. But if the moles are not killed they will destroy the lawn. Traps are freely advertised but seldom prove effective.

Mr. Hadkinson's foreman is a fearful foe to the mole. He watched Mr. Mole and studied him. The mole takes his meals regularly, at 6 a.m., noon, and at 6 p.m., and at any of these hours is the time to catch him.

The ridges made by the mole must be beaten down, and watched. When the mole goes over the route again the ridge is again raised. Then the process is easy. Take a spade, drive it in the ground across the moles' route and behind him. Unless this is done he will skurry underground and find safety in one of the deep holes that he has provided for emergencies. But the spade stops his progress and he may be easily dug out and dispatched. In less than a month the moles were banished from the agricultural section of the Fair.

PUBLICATIONS.

"How to Judge Architecture," is the title of a new work by Russell Sturgis, A. M., Ph. D., the well-known architect. The Baker & Taylor Co., Union Square, New York, are the publishers. The book consists of 215 pages, including 84 illustrations of celebrated buildings. It aims to be a popular guide to the appreciation of buildings. In the opening chapter, the author says: "The reader must feel assured that there are no authorities at all in the matter of architectural appreciation; and that the only opinions or impressions, or comparative appreciations that are worth anything to him are those which he will form gradually for himself. He will form them slowly, if he be wise; indeed, if he have the gift of artistic appreciation at all, he will soon learn to form them slowly. He will, moreover, hold them lightly even when formed, remembering that in a subject on which opinions differ so very widely at any one time, and have differed so much more widely if one epoch be compared with another, there can be no such thing as a final judgment."

ARCHITECTURAL LEAGUE OF AMERICA.

The annual convention of the Architecural League of America was held last month in the rooms of the St. Louis Architectural Club. J. P. Hynes of Toronto was elected the Speaker of the convention and J. B. Nettleton of Detroit, Secretary.

Reports were heard from the Executive Board, F. S. Lamb of New York, Chairman; from the Treasurer, Julius F. Harder, of New York; from the Committee on Publicity and Promotion, E. J. Russell, of St. Louis; from the Committee on Codes of Ethics and Competition, Julius F. Harder, of New York; from the Committee on Current Club Work, Chas. O. Pfeil, of Memphis, Tenn.; and from the Committee on Exhibition Circuit, the Committee on Education, and the Committee on Publicity and Promotion. A special report of the Committee on Civic Alliance was also read. This contemplates making the A. L. A. a member of an alliance of all the important civic and artistic organizations of the country.

A letter was read from the authorities at Washington, inviting the Architectural League of America to send delegates to the International Convention at Madrid: delegates were duly appointed.

The delegates then visited the Louisiana Purchase Exposition, took luncheon at the Administration Building, and were received by Mayor Wells, of St. Louis.

An address was then made by Mr. Isaac S. Taylor, Director of Works.

The Exposition Grounds were inspected by the delegates in the afternoon.

On Monday evening a public meeting was held in the Museum of Fine Arts. The exercises were opened with an address by Prof. Halsey C. Ives, Director of the Museum of Fine Arts. Then followed three papers on the "New Thought in Design", the opening paper, by Frederick S. Lamb, of New York, President of the A. L. A.; "The Influence of the Movement Upon Ornamentation;" by Mr. Claude Fayette Bragdon, of Rochester, N.Y.; "Its Effect Upon Construction;" and Mr. Hugh G. M. Garden, of Chicago, gave the concluding paper, "The Effect of Both Upon Architecture."

Tuesday morning was occupied by a business session of the convention at the rooms of the St. Louis Architectural Club; luncheon was then served at the Union Station Cafe, and in the afternoon the official business of the convention was concluded; the new president elected; and the place at which the next annual convention is to be held, decided upon.

In the evening there was a review of the parade of the Veiled Prophet from a stand in front of the Carleton Building; and before leaving the delegates were entertained at a symposium held in the banquet hall of the St. Nicholas Hotel.

The Executive for the ensuing year is composed as follows: Ernest Helfensteller, Jr., President; John C. Stephens, 1st Vice President; Wm. B. Ittner, 2nd Vice President; N. O. Vegley, Treasurer; W. T. Trueblood, Secretary; Prof. F. M. Mann, E. C. Klipstein, Ernest Helfensteller, Jr., John C. Stephens, Chas. O. Pfeil, Ernest J. Russell, Oscar Enders, E. G. Garden.

It was determined to hold the next convention at Pittsburg, in the months of April or May, next.

A vote of thanks was extended to the retiring President, Mr. F. S. Lamb, and to the Executive Committee.

A vote of appreciation of the courtesies extended by the Louisiana Purchase Exposition Company to the A. L. A. was also passed.

The thanks of the visiting delegates was expressed in proper form to the St. Louis Architectural Club, and particularly to its President, Mr. Ernest Helfensteller, Jr., for the able and hospitable way in which they carried out the task imposed upon them.

ONTARIO ASSOCIATION OF ARCHITECTS.

At the meeting of the Toronto Chapter held on the 3rd inst. the following resolution was adopted: Moved by W. L. Symons, seconded by G. W. Gouinlock: That the Toronto Chapter of the Ontario Association of Architects views with great satisfaction the acquisition of the Garrison property by the City of Toronto for the purpose of a park, and heartily endorse the proposal to employ an expert or experts to suggest a scheme for laying out the same in a proper manner, in connection with the development of a general system of parks, drives, street improvements and playgrounds. Numerous instances could be cited of the success of such method of procedure. Among the latest may be mentioned the City of Ottawa, and the City of Cleveland, Ohio. In the case of the latter city, some $20,000 has been expended in the preparation of a report and design for a most artistic scheme on generous lines, by three of the ablest experts obtainable, and the result, when carried out in its entirety, bids fair to be most successful, amply warranting the initial expense incurred. There is no reason why Toronto should not, in the course of time, have one of the most unique and attractive systems of parks and drives on this continent. The present is an opportune time to begin this development, and only by judicious forethought in the planning of the scheme can satisfactory results be accomplished. A scheme should be matured now even though it should take half a century for its final and full development.

Preparations are now in progress for the annual convention, which will be held on Tuesday and Wednesday, January 12th and 13th. The prospects are that it will be a most successful one. A special feature will be the exhibition to be opened in the rooms of the Association, on the first evening of the convention and to be continued for one or two weeks. Following the trend of popular feeling, the motto is to be "Made in Canada" and there is expected to be on view a thoroughly representative collection of drawings, water colors, photographs, decorative designs and sculpture, illustrative of Canadian architecture and art. Architects from all parts of the province should endeavor to make this exhibition a success, and it is hoped that in many cases special drawings will be prepared for the purpose. The committee in charge of the convention is now making arrangements for the programme, which should be appreciated by the members at large. A fitting conclusion to the convention will be the banquet to be held in the King Edward Hotel.

The members of the Toronto Chapter have made a new departure this year, as regards the Tuesday luncheons. They have joined with the members of the Engineers' Club, holding a combined luncheon, with the result of double the attendance and much good fellowship. If any special business affecting either branch demands attention, a withdrawal is made to the club rooms, after the luncheon.

THE TORONTO ISOLATION HOSPITAL.

To the Editor of the CANADIAN ARCHITECT AND BUILDER:

SIR,—I would respectfully call your attention to the new addition to Isolation Hospital now being erected. The addition is placed between the jail wall and south wing of old hospital—10 feet from latter and about 15 feet from former. The shed and yard where prisoners work is just under the hospital windows, while the women's work rooms are only a few yards farther away. The jail hospital and ward windows are in close proximity to the new addition, which is to be provided with a cold air fan to remove all contaminated air—blowing it out on a level with jail windows, so that it may not linger on the way and may be received fresh.

It is surely a disgrace to civilization to have this sort of return to the historical ghettos of ancient history, and will if possible make the hospital more of a contagious imparting center than it has been—where so many have come in with one disease and got another before they left—owing to interference with original plans of architect and want of realizing that an hospital for contagious diseases ought to be worked on different plans from those for the treatment of non-contagious diseases.

The law requires an hospital of this kind to be placed 150 yards from any dwelling, and the old hospital was burned down because it was only 140 yards from one dwelling. The new one is not 100 feet from hundreds of people, and guards and prisoners have to work and pass within a few feet of its windows. We have heard it proclaimed that 9 miles of still water in our deep lake is not enough to purify it. Now here is a case where as many feet of air is supposed to purify it. What is the given data for each?

I have said nothing of the blanketing of windows between new and old, with exclusion of light and air, and consequent harbouring of bacteria. I have said enough to show how careless some authorities can be.

Yours respectfully,
PLUMB RULE.

[EDITOR'S NOTE.—We have investigated the statements made by the writer of the above letter, and find that at least some of them are incorrect, and that there are special circumstances which ought to be stated. While the Ontario Health Act provides that a hospital for contagious diseases must be situated 150 yards from any dwelling, the Ontario Legislature granted a special Act permitting the placing of the original Toronto Isolation Hospital, as well as the new building now being erected, on the site which they occupy. As the Provincial Government are the owners of the jail property, it must be concluded that they did not consider that the inmates or officials of the jail would be likely to be affected by the proximity of the hospital buildings. The jail yards proper are sufficiently far away to almost prevent the possibility of infection reaching them through the open air space intervening. It is learned that it is the intention of the hospital authorities to ventilate the new building entirely by means of fans, and to keep closed at all times the windows facing the jail yards. The statement that the foul air from the hospita will be blown out on a level with the windows of the jail is hardly correct. The air will be drawn by suction fans into a ventilator and by fans will be driven vertically out of the ventilator at the top of the building at a height of 50 feet. This ventilator is sufficiently distant from the jail building to make it certain that the air thus discharged under pressure will be dissipated into the atmosphere instead of finding its way into the jail windows.]

The report of the Building Inspector of St. John, N.B., shows that thus far sixty seven building permits have been issued this year, and that in quality as well as quantity building improvements have surpassed those of any recent year.

Bids were opened for a school house in Indianapolis the other day, and the cost was $14,000 more than there was money to build with. Buildings in neighboring towns have overrun the estimates from 30 per cent. to 100 per cent. This is owing to two causes: First, an absolute increase in the cost of material and labor; second, an uncertainty as to the course of the market for material and labor. Strikes and rumors of strikes leave us at sea as to the future. The builder is not really disposed to take the short end of it.—The Clay Worker.

The Eiffel Tower in Paris, the removal of which at an early date was referred to in a previous issue, is 986 ft. high. In its construction were used 7,000 tons of iron, 2,500,000 rivets, weighing 450 tons, and 12,000 working drawings. The legs measure about 250 ft. at the base, while the platform at the top is 53 ft. square. The total thrust on the foundations is 565 tons, not including wind-pressure; under a maximum wind-pressure the thrust is 875 tons. The structure cost $1,000,000, of which sum the State contributed 60 per cent. the remainder being supplied by Mr. Eiffel, who has received for twenty years the profits from valuable concessions.

NOTES

The legislature of Oregon has passed a bill requiring the appointment of a board of examiners of plumbers in every incorporated city of 4,000 population.

A public subscription is about to be opened in Toronto for the purpose of erecting a monument to the memory of Toronto soldiers who fell in the South African war.

Mr. E. J. Lennox, architect of the new municipal buildings in Toronto, announces that the total extras on the buildings will not exceed $15,000. This must be considered a very satisfactory showing when it is remembered that the buildings cost upwards of $2,000,000, involving eighty separate contracts.

Ald. Curry, who is an architect, is urging the City Council of Toronto to adopt a number of amendments to the present method of assessment for local improvements. One is that suggested by this journal last year, viz., the placing of a special tax on the owners of vehicles. The owners of delivery wagons are chiefly responsible for the wearing out of the pavements and are most benefitted by good pavements, by means of which the cost of renewal of both vehicles and horses is greatly lessened. These are the people therefore, who should contribute most largely to the cost of good pavements.

SUBSCRIPTIONS.

THE CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States on the following terms: Architects' Edition, $3.00 per year; Regular Edition, $2.00 per year. The price to foreign subscribers is: Architects' Edition, 16 shillings; Regular Edition, 12 shillings. Subscriptions are payable in advance. The Journal will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrears of subscription paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of value to the persons in whose interest this journal is published are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publishers of any irregularity in delivery.

BUSINESS NOTES.

A representative of this journal had the opportunity recently of inspecting the new factory of the Canadian Heating and Ventilating Co. at Owen Sound, Ont. The company commenced to build on the first of June last, and now occupy the completed building, a substantial stone structure, with modern equipment for the manufacture of furnaces, radiators, stoves and ranges. The management of the company, which is capitalized at $200,000, is in the hands of Mr. J. Christie.

MOVING CARRARA MARBLE.

The marble quarries of Carrara, Italy, number about four hundred and give employment to nearly seven thousand men. Hard labor is the rule, for the distances separating quarry from quarry and the declivitous nature of the country make the use of machinery almost impossible. Hence, say a writer in Pearson's Magazine, have grown up the methods of the lizzatura, or workmen, who convey the marble over the roadless steeps that stretch from the quarries to the wagon track.

As soon as a great fragment of marble, detached by a blast, has stoped rolling, it is roughly squared into a block weighing, say, forty tons. Then the lizzatura set about getting it down.

Along certain lines of descent offering the least resistance a succession of stout posts has been firmly driven into the mountain side. The men, by means of crowbars and screwjacks, raise the block on to a soaped skid of beechwood. Before doing this they secure the block by means of three long kempen cables, with which they take turns around the posts. They pay out sufficient rope to allow the ponderous mass to slide over the soaped skids by its own weight, but not enough to allow it to gain too much momentum down the incline.

During the descent, besides the men tailing on to the ropes, two or more men are seated on the block. A man following closely on the wake of it hands them the skid just passed over, which they resoap and hand to a man who keeps just in front of the moving mass, to put down in its path, and so provide a continuous slipway. This last-mentioned worker has the most perilous task. If one of the cables parts at a critical moment, or if a mistake has been made in paying out or slackening them, he must inevitable be crushed.

It is an amazing fact that in former times the lizzatura used only one cable to hold back the load, until the government, rightly regarding their's as a dangerous occupation, passed a law that not less than three cables should be employed. On an average, this work is responsible for three deaths a year, but for the most part the finest discernment, judgment, coolness and skill are displayed by the lizzatura, who work in gangs numbering twelve to fifteen men.

It is really astounding to see how these workmen handle the huge masses of marble, without machinery of any kind but crowbars and jackscrews. Pieces of forty tons' weight, with those simple implements, are loaded on bullock wagons and carried down to Carrara all the way by road—a terribly toilsome process, for the mountain road is more like a bed of a torrent than a beaten track.

NOTES.

Up to the first of October the value of new buildings erected this year in Vancouver, B.C., as represented by the building permits is $1,300,000. The total for the year is expected to reach a million and a half.

Interest has been aroused by the announcement, as the result of a prolonged series of experiments, of a method of so treating timber as to secure even from soft wood a largely increased toughness and hardness. The process is described as one of vulcanizing, comparable in some respects with Bessemer's process for converting iron into steel, and is the invention of Mr. Powell a Liverpool merchant. The treatment to which the timber is subjected is, roughly speaking, that of saturation at boiling point with a solution of sugar, the water being afterward evaporated at a high temperature. The result is to leave the pores and interstices of the wood filled in with solid matter, and the timber vulcanized, preserved and seasoned. The nature of moderately soft wood, it is claimed, is in this way changed to a tough and hard substance, without brittleness, and also without any tendency to split or crack. It is also rendered remarkably impervious to water. Hardwood similarly treated derives similar benefits. Moreover, it is claimed that the process may be completed and timber turned out ready for use in a few days.

on plumbing equipment and gas and electric lighting fixtures and learn what wonderful qualities and values we are prepared to offer to you. We want you to see the Morrison lines before you place an order elsewhere and we know that such an inspection will convince you of the striking superiority of our offerings.

JAMES MORRISON BRASS MFG. CO., LIMITED
TORONTO, ONT.

The Canadian Coral Marble Company
LIMITED

THE above cut shows sample of **Floor, Columns, Wainscoting, etc.,** supplied by the **Canadian Coral Marble Company, Limited.** We respectfully call the attention of every Architect and Builder in Toronto and elsewhere to the class of work done by this Company.

The new and improved tile floors are the talk and wonder of every person who has had the privilege of inspecting them. The fancy floors have no equal either for style, durability, or as a sanitary floor. The price is most reasonable considering the superior merit of the work as compared with other tile flooring. See the product and be convinced.

The Company has also acquired all the rights for the Dominion of Canada, from Mr. Guelton for the manufacture of Mycenian Marble, and any person having made himself acquainted with the class of work done by Mr. Guelton knows that it has no equal anywhere, his work having all the appearance and durability of the best Onyx

Every Architect and Builder should consult the Company, see the material and obtain prices.

The Company is now prepared to execute orders in all the different designs of Flooring, Wainscoting, Mantels, Columns and other Interior Decorations.

Correspondence solicited.

Our Students' Competition.

Architects will confer a favor by directing the attention of their students to our Students' Competition, particulars of which are printed in this number. Every industrious and ambitious student should find it profitable to take part in this competition.

Giving Value to Waste Material.

A few years ago brickmakers in Toronto threw away as useless a considerable quantity of what are known as "clinker bricks," i. e., bricks uneven in color and shape and exhibiting protuberances on their surfaces. These peculiarities are due to the bricks being placed in the arch of the kiln where they are exposed to the greatest heat. An architect in looking one day at a pile of these refuse bricks thought he saw possibilities in them, and forthwith bought sufficient of them to build himself a house. The appearance of the house was pleasing and in contrast to the ordinary run of work. Other architects then saw a value in the clinker brick and began to use them. The demand so increased that the brickmakers themselves came to see the value of what they had been accustomed to regard as a waste product and the price was advanced until now "clinkers" bring two dollars per thousand more than standard first quality.

Arbitration of Building Disputes.

The Building Trades Council of Toronto have applied to the Ontario Association of Architects to have a clause inserted in all contracts providing that any disputes which might arise between contractors and workmen must be settled by arbitration. At the last meeting of the Toronto Chapter this request was fully discussed, after which a resolution was passed declaring that while the architects were heartily in favor of the principle of settling disputes by arbitration they could not advocate the insertion of an arbitration clause in contracts so long as the Building Trades Council or its component unions could not be held legally responsible for any agreement into which they might enter.

Fixing Responsibility.

Where a number of contractors representing various trades are engaged on a building, an effort is made to shift responsibility for any neglect or damage from one to another. Under these conditions the architect, who of course cannot be constantly on the work, experiences great difficulty in placing the responsibility on the proper shoulders. He has sometimes to spend much time and effort to get the contractors together in order that the difficulty

may be threshed out and if possible the blame put where it should belong. Even when a meeting is secured, the object is not being attained, and the guilty party goes free. Some architects have to a large extent got over this difficulty by including the roofing and tinners' work in the carpenters' contract. Some are now considering the advisability of making the roofer responsible for any damage which may be sustained by the carpenter or plasterer by reason of leaks in the roof.

The Value of Simplicity.

"The older I grow the greater is my admiration for simple things," said an architect of conspicuous ability to the writer recently. He added that as a rule people now-a-days do not want simple things. All sense of repose is destroyed by crowding modern houses full of ingle nooks, bow windows, fire places, &c. As a result there remained no wall surface, no place to put anything; "You can't sit on the fireplace, you know" he remarked, and characterized as "rot" the idea that a modern house should have a Turkish room, a Japanese room, etc. On the contrary the house throughout should have one character. Much of the recent architecture in the United States has actually been spoiled by the fact that the architects had too much money at their disposal, and therefore were not compelled to exercise restraint in their designs. That the public taste has been perverted is illustrated by the remark of a prominent citizen of Toronto, when referring to the new residence ot another wealthy citizen, the exterior of which is characterized by simplicity of design, that he did not want HIS new house to look like a barn.

Up-to-Date Building Methods.

Swiftness is a predominating charactistic of this age. Every device that will save time and labor is eagerly sought for and when found is quickly adopted by progressive business firms. Sometimes we think that many things of perhaps greater importance are sacrificed to speed. However this may be, it is undoubtedly true that when the majority are aiming at accomplishing their work with the greatest possible despatch, the man or firm who pursues a leisurely gait, is likely to be left behind in the race. It is therefore gratifying to observe the builders falling into line with other departments of industry by adopting modern business methods. One of these is the placing of a telephone on the job, so that constant communication may be had by the foreman with the offices of the architect, the contractors and supply firms, and vice versa. The value of the time which may thus be saved is considerably more than the cost of the telephone service. Wide-awake builders are coming to recognize that by adopting every possible time saving device they may add considerably to their profits and be able to underbid the contractor who still pursues old fashioned and out-of-date methods.

Asbestos in Building

It is interesting to learn that the product of the asbestos quarries in the province of Quebec is in France being manufactured into bricks, roofing slabs and outside and inside lining material for buildings. At an Exhibition of dwelling houses held in Paris in August last, a model was shown of a modern house built entirely of asbestos bricks, which are claimed the advantage of being absolutely incombustible and unattackable by acids, while at the same time bad conductors of sound, heat, cold and electricity. They are composed entirely of asbestos, lime, and silica in strictly defined proportions, and the substances intimately mixed by special machines, are compressed in the form of ordinary bricks by powerful presses. The bricks are afterwards subjected to the chemical action of high pressure steam, owing to which a double silicate of lime and magnesia is formed. These new building materials, the structure of which is perfectly homogeneous, are said to be equal to the best clay bricks as regards resistance to crushing stress. They are easily cut with the trowel, and take mortar well, while the thickness of joint is reduced to a minimum owing to the perfectly regular form of the brick. The external appearance is that of dressed stone ; and, as the bricks can be colored unalterably while in the state of paste, they lend themselves admirably to polychrome decoration.

British Exports and Imports of Building Material.

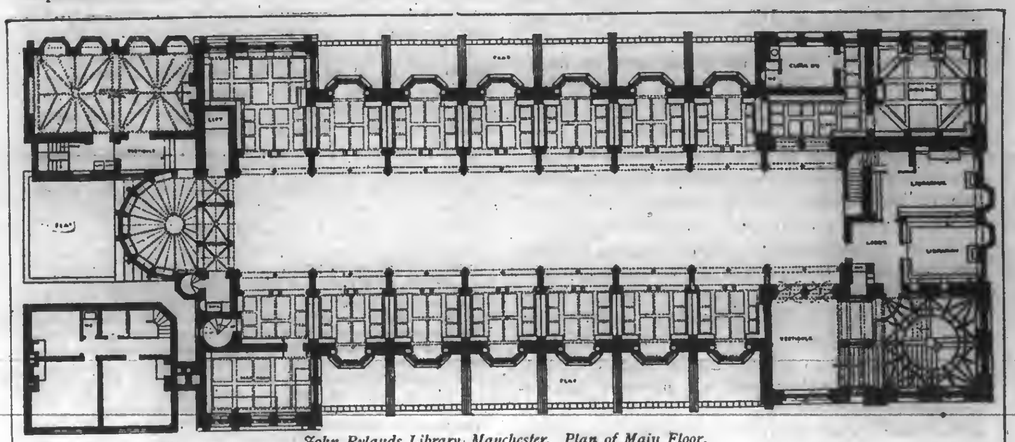
The Board of Trade have recently published a blue book, from which some particulars are extracted relative to this subject. One of the most startling facts disclosed from the British standpoint is the tremendous drop in the exports of cement; shipments to the United States in 1902 being only one fifteenth as great as in 1901 and to other foreign countries, about one sixth. While the exports to the colonies are reported to have been regular, it is a well known fact that the Canadian market has been largely supplied by home manufacturers and by the product of United States mills, while in 1901 Australia, Natal and the Cape are said to have purchased from foreign manufacturers to the value of £20,000. The shipments of bricks to the colonies increased by one half from 1892 to 1902. Very little if any of this material found a market in Canada, as our manufacturing resources in this line are ample. In painters' materials the exports both to foreign countries and to the colonies substantially increased. Increased quantities of manufactured articles of iron and steel were also sold in the colonies; as well as stones and slates. The foothold which foreign manufacturers ot iron and steel are getting in the British market is shown by the import figures. The quantities ot bar, angle, bolt and rod iron, unwrought iron and steel, iron and steel girders, beams, joists and pillars imported into Great Britain from Germany, Holland and Belguim increased from 99,942 tons in 1899 to 529,970 tons in 1902. The value of these imports increased during this period from £667,528 to £2,810,723. The imports from the United States increased from 71,608 tons in 1899 to 172,105 tons in 1900, but, owing to the extraordinarg home demand has felln in 1902 to 3,853 tons. The present slackening of this demand will no doubt lead to another vigorous assult on the British market. These statistics are now being very carefully dissected and considered by the Journals representing the various branches of trade in Great Britain, in the light of Mr. Chamberlain's preferential tariff campaign. Viewed from this standpoint they should also have an interest and a meaning for Canadians.

NOTES OF TRAVEL.—VII.

The John Rylands Library, Manchester.

If this is not the most interesting recent building in England, one would like to see the building which is of greater interest. Mr. Basil Champneys, the architect, appears to have had a pretty free hand in the matter of both expense and time, (the library was nine years in building), and, though a definite lead was given which suggested the style, it was a style which suited the designer and he has worked quite freely in it. It is gothic; but English gothic, which still seems quite at home in England, when properly handled. The plan is rather suggestive of a church plan and the style is early, yet the building has a thoroughly modern air ; there is no archaic feeling about it.

The Library is rather a repository for rare books than a place for distributing current literature. Its strength is in early printed books, an "unrivalled collection"; a collection of Aldines, "believed to be the finest in existence"; a Bible collection comprising, besides some MSS., copies of the successive printed editions; in first editions of the classics of English literature; early maps and atlases; the Early Fathers; early Service Books; in fact in books which are the fountains of study in their various fields and are consulted only by scholars. For this purpose the building is perfect.



John Rylands Library, Manchester. Plan of Main Floor.

The plan of the main floor (taken from THE BUILDER) which is shown here, shows the distinctive feature of the building in the way in which the body of the great Reading Room is recessed. The building is free on both sides, lying between two narrow streets ; but ancient lights in the premises across these streets; and the need of abundant light in the reading room, required it to be set back about 12 ft. from the building line of the sides. The ground floor rooms are kept in the centre also; they are approached by vaulted corridors along the sides, (the roofs of which appear in the plan), which are kept down to 9 feet in internal height, so that there is space (some 10 feet) above them for lighting the ground floor rooms. These rooms are a lecture room—close to the entrance—committee rooms, and minor rooms for storage of books and for reading. The ground floor is one flight of steps above the entrance, which has a level of its own near the level of the street. The entrance, which takes the whole space under the Librarian's rooms in the plan, was intended to be imposing, but has failed because the stairs are not visible on sight and are in a chamber which is too close and contributes but little light to the entrance. If the stairs were open, and the light came from there, it would have been a fine entrance hall; as it is it is only a vestibule, large but gloomy. There is no hall.

The main floor, which is both reading room and book room, is shown in the plan and a photographic view is given in the illustration sheets. The books are contained in alcoves. There are two tiers of alcoves, each with a bay window filled with square leading of a delicately tinted whitish green glass, with a bull's-eye in every quarry. The upper alcoves are reached by a narrow stone gallery which makes below a sort of columned and vaulted vestibule or screen to the alcoves on the main floor. This gallery runs all round; the piers, or buttresses, which carry the vaulting, are pierced with openings for its passage. There is no continuous wall; the two stories of bay windows dispose of the continuity of the outer wall; the vaulting is carried on piers, about 2 ft. 3 in. by 6 ft., which are stayed by the gallery, by the arches and vaulted roof of the upper alcove, (which is itself buttressed between the bay windows), and by arches turned between the piers themselves, over the clear story windows. The alcoves are not divided by walls but arched openings filled by bookcases; and the floor between the two tiers, inside of the gallery, is of wood. The two tiers of alcoves are only 30 feet high and the main vaulting is 44, so that there is room for a large clear story window. No space is occupied by a wooden roof for there is none over either aisles or nave; the stone vaulting is finished to a level with concrete and covered with asphalt. There is no point of view from which the roof can be seen, except perhaps in front; and a pair of towers, with, I believe, a parapet wall between, obstruct any view from this point. There is something unusual also in the position of these towers. They are not set over the outermost area of the double squares, which flank the entrance on both sides, but over the inner square of each; the outer square in each case is a lantern, nestling, as it were, at the base of the tower, (an odd-looking arrangement,) and lighting in one case the staircase and in the other (apparently) the Bible Room. The towers have no internal signifi-

cance. The explanation of their being set back in this way is the necessity of fitting the profile of the building to the angle required by rights of light on the opposite side of the way. The space between the towers, occupied by the Librarian's rooms, is roofed over at the gallery level; so that there is a large window, rising from the gallery to the apex of the vaulting, at this end as well as at the other.

To return to the interior of the Library proper which is the essential part of the building—the central portion of this hall, the nave as it were, is 20 feet wide 44 feet high and 125 feet long to the terminating window, or 148 feet long, counting in the apse, which exends the floor level but not the roof, as it is vaulted over to a lantern about the height of the gallery. In the same manner the alcoves extend the width another 20 feet on each side, counting in the projection of the bay windows. The actual sitting space in the alcoves omitting the bay windows (6 ft. wide by 4 ft. 8in. projection), and the vestibule formed by the colonnade carrying the gallery, is 10 ft. by 12 ft. inside of the bookcases.

The bay windows of the alcoves are panelled in oak, (linen pattern) and the ceilings of the lower alcoves are beams and plaster, but this is the only wood that appears in the construction; all roofs are vaulted in stone and the tracery of the large windows is stone. The building is essentially stone and appears to be all stone. The colour of the stone which is both well chosen and well handled, is therefore a great part of the beauty of the room. The stone used for the interior is Shawk, a stone that varies in colour from grey to a delicate tone of red. In the earlier part of the building operations it was procured with the varied tints closely mingled, so as to give the stone a mottled appearance; but this gave out in time; the colour seems to have then appeared in larger masses in the quarry, so that the stone delivered was no longer mottled but in pieces of homogeneous colour, varying however from one another to the extent of the opposite poles of the colour exhibited in the quarry. The bold juxtaposition of lightest tint and darkest tint in the use of the stone, after it came in this way, is satisfactory from every point of view; it relieves the building as a whole from monotony of colour, and, as a matter of closer inspection, it brings out the jointing, always a great part of the beauty of stonework. If the accompanying illustrattion of one of the alcoves reproduces correctlv the variation of tint in the stones, (which is even more delicate in the photograph than it is in reality, but it must be remembered that the colours are delicate) this will be seen. In the vaulting a banded effect was made, which also seems constructionally suitable there.

The statues, which stand on an attached column in the centre of each bay of the gallery, are of the same stone. They are portraits of eminent men of different countries and ages, in the several departments of Literature, Science and Art. The same idea is carried into the large windows at each end, which have each twenty portraits of intellectual lights, ranging from Moses to Thomas Carlyle. These are the only stained windows in the building, and in these it is only the figures that are stained. All other windows are leaded in squares, glazed with the most delicately tinted, whitish green glass, with a bull's eye in each quarry.

As to fittings:—The most noteworthy are the dust-tight doors of the bookcases. These are made of gunmetal, about an inch square, and carry a sheet of plate glass 2 ft. by 9 ft. 9 in., without crossbars; there can be none because, the shelves being set to varying heights it would be impossible to make the sash bars range with them always. The exclusion of air (i.e. dust) was perfected by insertion under a fillet, of rolls of velvet made elastic by the insertion of cotton wool. It appears, however, that the absolute exclusion of air, which doubtless means the prevention of change of air, is not good for the books. Air is filtered by means of cotton wool, as it enters the building, and arrangements have been made for the application of water sprays, if they are found necessary. Gas is absolutely excluded, the reason given—that it "takes all the moisture out of the air and forces off the backs of the books in an extraordinary way"—is worth noting for application in another direction; heating arrangements that take all the moisture out of the air must have provision, in a library for putting it back again. The fact is that the best way to make the air of a library suitable for books is to see that it is suitable for human beings; the best conditions for health seem to be the same for both the librarian and his books.

W. A. Langton.

ILLUSTRATIONS.

Referring to the competitive design for Vancouver General Hospital by John J. Honeyman, reproduced in the illustration pages of this number, a word may be said regarding the plan:

The three rear ward pavilions have open arcarded basements to allow of air movement between the buildings. While the plan shows the disposition of the main buildings, a block plan of the whole site (606'x400') would show in the rear a mortuary, isolation ward, nurses' home and steam laundry, with dynamo, heating plant, etc., disposed with driveways and approaches complete. The front facade as shown faces due north and has a commanding view of the whole of Vancouver, on the north side of False Creek Inlet.

OFFICE BUILDING FOR MESSRS. J. J. RILEY & SONS, ST. JOHN STREET, MONTREAL. —FINLEY & SPENCE, ARCHITECTS.

The building is designed in the Old Colonial style, and the front elevation is carried out in white marble and Roman brick; being the first example of this style of work in Montreal. The frontage of the building is forty-six feet. The building has been designed especially to suit the needs of the owners, the main entrance leads directly from the street to the ground floor, which forms a large public office fifty feet deep by forty feet wide, with the private offices of the firm to the left of the main entrance.

The first floor of the building forms a wide gallery which is carried around all sides of the building leaving a large area twenty feet square with a sky-light of the same size in the roof. As the only side lights to the building are the windows in the front elevation, this skylight gives a splendid light to every part of the building, and at the same time gives a very artistic effect, as the ceiling light is in the shape of a large dome of leaded glass giving a very handsome appearance. The balcony is reached by a wide flight of stairs in the rear of the offices; the height from the ground floor to the balcony is fourteen feet and the height from the ground floor to the ceiling light is thirty feet, which gives the whole office a very lofty appearance.

The entire building is finished in quartered white oak. The counter dividing the clerks from the public is of a handsome design and finished on top with a bronze grille to a height of seven feet from the floor.

The electric fittings throughout were designed in conformity with the rest of the work and add very much to the general appearance of the building. In the rear of the offices are situated two tiers of vaults, each vault about ten feet by seven feet.

In the basement is situated the directors room, store-rooms for books, papers, etc., and private and public lavatories, heating plant, coal, etc., etc.

No expense has been spared in order to make the building thoroughly first class and up-to-date in every respect.

The building was designed and carried out under the supervision of Messrs. Finley & Spence, architects.

Mr. J. Wilson Gray, architect, is one of the twelve candidates selected by the Citizens' Committee for the New Educational Board of Toronto.

Old French Houses.

TORONTO MASTER PLUMBERS' ASSOCIATION.

The first monthly entertainment meeting of the master plumbers and supply men of Toronto was held on the evening of November 23rd in the association rooms, 21 Richmond street west. The room was handsomely decorated with flags. About three hundred members and friends assemhled. The meeting was called to order by Mr. Fred. Armstrong, who, after expressing thanks for the large attendance, gave due credit tc Mr. Clapperton, who had been the means of having instituted such social gatherings every alternate meeting. Mr. Armstrong then delivered the following address, which was listened to very attentively by all present:

At a meeting of the Association it was moved by one of the members that each alternate meeting night of the Association be set apart and devoted to social purposes. This idea emanated from a feeling that it would be wise to vary the ordinary routine of business so that it would not become monotonous. At the same time it was not thought desirable to stray too far from our proper field, but to always keep in view the fact that our Association was formed with some definite object in view and for some beneficial purpose. So it was suggested that part of the evening should be devoted to the reading of a paper or the delivering of an address and part to social or entertainment features upon which the committee would decide. I have been honored by the chairman of the committee in being requested to deliver the first address and to take charge of the first night's proceedings, and I may very frankly confess that I accepted this task with no little trepidation, realizing that much of the success of future meetings would depend upon the success of this the inaugural one.

In discussing matters relative to these meetings it was thought advisable that a paper should be read upon some trade question, but I have looked carefully into the matter and have come to the conclusion that upon this occasion it would be better that we should simply have a heart to heart talk upon a subject which is most interesting to every member of the Association, and if what I can say will interest the members I have no doubt it will lead to further addresses or papers being read on trade subjects by the other members of the Association who are more able than I to deal with such weighty matters.

For to-night, therefore, we will talk about our Association, its objects and aims, and apply what I have to say to all those who are interested, directly or indirectly, and endeavor to prove that an association such as we have formed is beneficial not only to master plumbers but to the supply man, to the architect and to the general public. I only regret that more of these are not present to-night so that they might learn that the master plumbers of this city whom they have for some time regarded as a band of pirates sailing on the high sea of commerce holding up the public and making them walk the plank to the tune of higher prices is a body of men intensely interested in the uplifting and upbuilding of a calling which through neglect has fallen from the high position it should occupy until it is looked upon by many with much ridicule and made the butt of every cheap wit. It is our work to alter that opinion, but we must first learn to respect ourselves before we can hope to command the respect of others.

Let us consider the Association as it appeals to and is of interest to the supply man. But first let me say at by Association I do not mean any body of men who are gathered with the sole object in view of enhancing the value of any public commodity. Such a combination was never intended. When the Master Plumbers' Association was formed and since its formation the members have endeavored to discuss every question from an ethical and social as well as a commercial standpoint. Its members are willing to learn and have been taught by the experience of others that in order to do business it is necessary to consider all of the details in connection with that business. They have learned that the question of percentage is a most elusive one and that there are certain fixed charges which must be added to the first cost of an article before it becomes marketable or before they can arrive at the real cost. The object of the Association is therefore to discuss these matters, to consider the proper amount to be charged as a natural and uncontrollable expense in conducting business; to point out the shrinkage which occurs, to make provision for uncollectable accounts, and then consider what is a fair and equitable charge.

The manufacturer and supply man can surely rest assured that they will be paid for their goods when dealing with a body of men thoroughly conversant with business principles, taught the value of doing business in a business-like manner, and not engaged in any system of ruinous competition.

It is also apparent that where all of the men engaged in the business gather together to talk matters over, there will be a general desire to uphold the character of the goods they are handling and no striving for cheap products. Every man in the business will endeavor to use as good an article as the means of his client will permit. It will not therefore be necessary for the supply-man to take chances in the production of cheap articles of uncertain character when he knows that every member of our Association will besitate to recommend anything that does not comply with what the Master Plumbers' Association deem essential for the making of a thoroughly good job. If the supply-men have only to supply good material which they are certain will give them no trouble, to men who understand their business and do their work properly and receive a fair compensation therefor, it is certain that risks are reduced to a minimum, and if they make concessions to members of our Association, it is because they recognize the great benefit it will be to them in conducting their business.

Let us for a moment turn our attention to the architects. We are largely indebted to the good services of these gentlemen for much of the progressive and up-to-date plumbing which is installed in dwellings to-day, and it should not be necessary to use any arguments to convince them that an Association is a good thing. In the city of Toronto there are I believe two associations of architects and every reputable member of that profession belongs to either one or the other. Possibly the most convincing argument which they use is the statement that membership in their Association is an evidence of the ability of its members. If imitation is the sincerest kind of flattery, we pay these gentlemen a compliment in following the good example they have set us in forming an Association where we are just as discriminatory regarding our membership as they could possibly be. We take no man into our Association who is not duly accredited and ultimately hope to arrive at that state where membership in our organization will also be an evidence of a man's real worth and ability.

But there is another phase of the question. The architect designs and prepares specifications but the construction is in the hands of the contractor, and unless there is harmony of interest between the architect and the contractor the best prepared plans and specifications may result in defective work. How can we best effect that harmony of interest. I answer by our Association. Let us endeavor to interest the architects. Let us show them we are proud of our Association; explain the good work we are doing; solicit their assistance, have joint meetings; discuss technical features of plumbing, heating and ventilation and apply our practical knowledge. The result will be that the very best class of work will be done in the city of Toronto. It is good to-day but we can make it better, and who shall say that an association of interests such as I have described will not be a benefit to the architect.

The general public as a rule look with distrust upon combinations, trusts and associations. They say they prevent com-

petition. We answer that our Association does not prevent honest competition but only that which allows a man to figure on work at less than its cost and take a chance that he will be able to scamp it to recoup himself for the loss. It prevents the competition that induces bad work, endangers the life of the occupant of the house and brings many other evils in its train: but fair and honest competition is just as keen as ever it was. The Association merely says that a man shall receive sufficient for his work to enable him to give his undivided attention to every detail in connection therewith, so that when the work is finished it will be perfect in all its parts—an evidence of the ability and skill of the plumber and a credit to the association to which he belongs. There are many other advantages which will accrue to the general public from our Association, but if they receive no other benefit than the fact that they will be assured of good and sanitary plumbing then our association will have accomplished a great deal and the public will have received a most inestimable benefit.

And now let me ask the members present, is the Association a benefit to you? Have we done well in forming our Association? Has it stopped the habit of scrambling after the pennies and awakened you to a full realization of the position you should occupy?

Do you not find that to be a good member of the Association you must make a careful study of the laws of hygiene and sanitation and that you must be familiar with heating and ventilation in all its branches, that you must understand the physics of your profession as well as the practical application of all rules that govern our trade. If you are a good member you will become an expert in all its branches, be reliable and trustworthy. Your best efforts will be given to the uplifting and upbuilding of your business. Your best services will always be at the command of the public but you can demand, and will receive a fair compensation therefor. You lose nothing by being a member of the Association and you have everything to gain. It enlarges your mind and your vision is not dimmed by the petty jealouises that sometimes exist between competitors in the same business. All are equal in the Association. One man is as good as another. A healthy rivalry exists and competition is based on real merit and ability and each man's business grows and prospers according to his individual efforts. Such is the work of our Assnciation. May it continue to grow and prosper. It has had great growth, wonderful development and will grow until it reaches the ideal state I have outlined, if every member is true to himself, true to his organization and obedient to the laws of our Association.

The programme of the evening consisted of songs, recitations and speeches by members, aided by Mr. Bert Harvey. The speakers of the evening included Messrs. Fiddes, McMichael, Anthes, Malcolm. After expressing their gratitude for the enthusiastic way in which the members had worked to organize the Association they touched upon points in Mr. Armstrong's address and expressed their desire to see the Association grow so that it would not only be of benefit to themselves but to the general public.

A unanimous vote of thanks to Mr. Armstrong for his able address was adopted.

The singing of the National Anthem brought to a close a very enjoyable evening.

TESTS OF MASONRY PIERS.

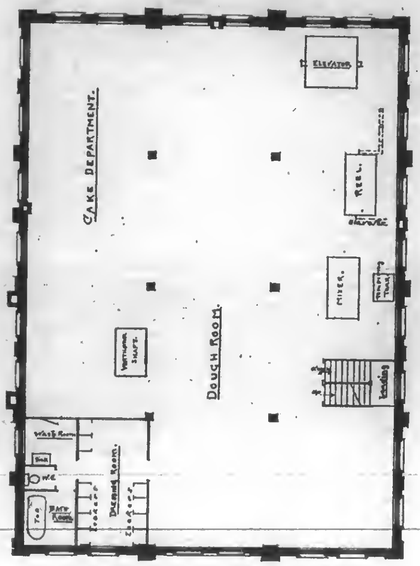
Several years ago the Austrian society of engineers and architects made a very important series of tests of full sized arches brick, stone and concrete, and the report of these trials, together with the accompanying analysis, proved a most valuable contribution to engineering literature. This work has now been supplemented by some important tests upon the strength of masonry piers, the tests being made under the supervision of the same committee which conducted the arch tests, the results being published in a recent issue of the Zeitschrift des Oesterr Ingenieur and Architekten Vereines.

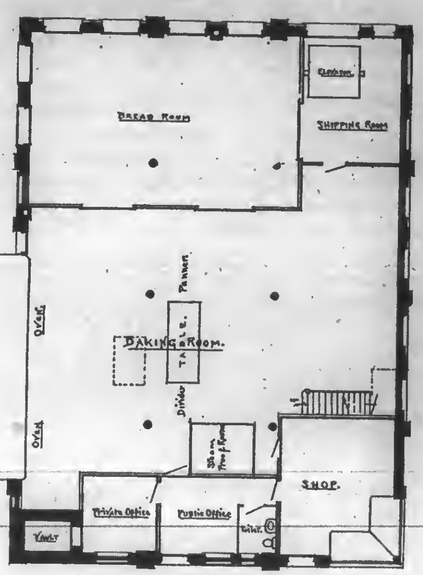
The tests were made in all cases upon one-half metre square in cross section and one metre in height, the pressure being applied by means of a 1,200 ton hydraulic press at the Poldihutte at Kladno. The report gives an illustrated description of this press, which was originally constructed for forging steel, and which had already been employed for testing on similar work by Herr Ludwig Huss, former member of the arch-test committee. The press was carefully calibrated to determine its internal frictional resistances, and the guages upon which the pressures were read being also calibrated, it was possible to determine the true pressure upon the test piers very closely.

Various kinds of piers were subjected to the tests, for the details of which the reader must be referred to the original report. Among those tested were piers of granite, sandstone, concrete, common and reinforced, and brick. The reinforced concrete construction was tested in two different types, one having embedded in it vertical wire rods 12 m in diameter, and the other containing wire cages, of which the principal members were parallel to the surfaces of pressure. In all cases much care was taken to insure that the load should be central, with the exception of certain tests which were purposely made to determine the effect of eccentric loading. The records were taken at the moment of the appearance of the first cracks, and at the time of ultimate crushing, these results being fully tabulated in the report.

The tables are very full in details and but a few results can be given here. Thus a pier of hard bricks laid in Portland cement sustained, after six months, a load of 1,365 pounds per square inch before cracks appeared, and crushed under 2,275 pounds. Granite blocks laid in Portland cement crushed under 8,100 pounds per square inch, while piers of sandstone rubble, laid in Portland cement, showed cracks under a load of 2,750 pounds, and crushed under 3,200 pounds.

The most interesting tests, however, were those which showed the resistance of ordinary and reinforced concrete piers. A pier of solid concrete after 3½ months, crushed under 1,780 pounds per square inch, the rupture taking place almost without warning cracks. A similar pier reinforced by the insertion of vertical wire rods held together by circumferential bands, and tested also after 3½ months stood a pressure of 2,470 pounds per square inch before the appearance of cracks, and crushed only after the application of a load of 3,800 pounds. Even then the pier did not altogether give way, the core remaining partially unbroken. The results of these tests showed the importance of placing the metal reinforcement where it can act to the best advantage. A moderate increase in the strength of the circumferential bands would have added greatly to the strength of the whole pier without adding appreciably to the cost, while the large margin of strength remaining after the appearance of the first cracks show how structures constructed on this principle may be made free from sudden disaster. The care with which these tests were made, and the fullness with which the results are recorded, render this report a valuable document, worthy of association with the large report of the same committee upon arch tests and it adds one more to the many contributions to engineering knowledge by the Austrian Society.





BREAD FACTORY FOR WM. LEES & SON, HAMILTON, ONT.—F. J. RASTRICK & SONS, ARCHITECTS.

RADIATION OR PIPE SURFACE REQUIRED FOR BUILDING, HAVING CONSIDERABLE VARIATIONS IN CONSTRUCTION, SIZE AND TEMPERATURE.*

Mr. Jones said he had not, up to the present time, met with any work that dealt with this difficult subject in an exhaustive manner, and whilst no one appreciated more fully than he did the excellent work of Mr. Chas. Hood, Mr. W. J. Baldwin, Mr. T. Box, Prof. Carpenter, Mr. F. Dye and others, who have given much valuable information, he has also felt that the discrepancies in the various rules and formulæ were so great that a nearer approach to uniformity was sorely needed, and he trusted that the writers referred to would accept these criticisms in the most friendly spirit, and with the assurance that his sole object was an earnest desire to approach a solution of this difficult subject. He would not confine himself to destructive criticism, but would endeavor to crowd as much constructive information as possible into his short paper, in a manner so specific as to give the leading members of his profession food for thought and ample scope for criticism.

He was of opinion that the conflicting opinions had arisen from several causes: First, the uncertainty that existed in the cooling or losses of heat through the glass. Second, by the use of constant, theoretical calculations, or multipliers, which would apply under equal conditions, but were only misleading where extreme variations of temperature existed. Third, that the calculations had not been verified by actual tests.

The results of experimental cooling tests with an iron tube and a glass tube of approximately the same size, exposed at the same time to outside air under similar conditions, were that, with a cast iron tube, the units per super foot, per degree difference per hour, were 1·99, while with the glass tube the figures were 1·72.

What he desired to point out was, that with considerable variations in temperature, any constant or fixed multiple was sure to result in error, because the conditions change with the variations in temperature.

All the authorities referred to were probably correct for stated conditions, and for a small range of temperatures, but he would endeavor to show that for different classes of buildings, and especially for high temperatures, the discrepancies were so great and so confusing that a combined effort should be made to obtain a nearer approach to accuracy.

The cooling atio, or loss of heat by glass, varied so enormously according to the difference in temperature, that the want of unanimity in the tables by different authorities was not at all surprising. Box, T, gave a loss (in units per sq. ft. of glass, per degree difference per hour) varying from ·306 to ·41 for greenhouses and ·504 to ·53 for windows. Professor Carpenter gave ·91 to ·98, while various other authorities, English, Continental, and American, varied from ·776 to 2·248. The difference between the highest and lowest was 630 per cent.

Again, in comparing formulæ, the various authors differed to practically as great an extent. Most of the published rules for obtaining the feet super of radiation were complicated, involving intricate calculations, and occupying more time than could ordinarily be given when preparing estimates. There would be no objection to this, providing the results obtained were such as to justify the extra time and trouble, but, so far as his experience went, this was not the case, for the results were frequently less accurate than those obtained by some simple formula, besides which complicated calculations were apt to lead to mistakes, and his object was to give some simple data that could be quickly grasped by the busy man, and that should give fairly reliable results under varying conditions.

(Here followed six comprehensive tables giving the heat ratios [or multipliers] for horticultural buildings. The figures cover the subject very fully, giving the superficial area of heating surface required to give internal temperature of from 40 degs. to 90 degs. Fahr., with external temperature of from 0 degs. to 50 degs., with the water at six different temperatures, from 150 degs. to 200 degs. Fahr. Following these tables are explanatory examples, also reference to other authors, showing that different authorities vary to the extent of nearly 100 per cent. in the radiation recommended for a given area.)

A rule for ordinary brick buildings Mr. Jones stated to be as follows:—To obtain 60 degs. inside when 30 degs. outside; water at 170 degs.—

Glass (G.) feet super. ÷ 6
Exposed Wall (W.) " ÷ 12 } = Feet super. radiation for 60 degs.
Cubic Capacity (C.C.) " ÷ 120 } inside when 30 degs. outside.
For rooms under 5,000 c.ft. capacity.
" " " ÷ 140 " 5,000 to 25,000 " "
" " " ÷ 150 " 25,000 to 100,000 " "
" " " ÷ 160 " over 100,000 " "

The above rule is for ordinary ventilation with one change of air per hour. If two or more changes, add cubic capacity ÷ 200 for each additional change.

In small rooms the glass and wall surface is proportionately greater than in large rooms, and in the latter the walls are thicker and the loss proportionately less, so the divisions are proportioned to meet these changed conditions.

*Abstract of Paper by Walter Jones, presented before the Institution of Heating and Ventilating Engineers of Great Britain.

EXAMPLE.—Suppose a room has 50 ft. of glass, 500 ft. exposed wall, and 5,000 ft. cubic capacity.

G. feet super. 30 ÷ 6 = 8
W. " 500 ÷ 12 = 41 } = 84 ft. super. radiation to give 60 degs. inside when 30 degs. outside and water 170 degs.
C.C. " 5.000 ÷ 140 = 35

Suppose the same room requires two or more changes of air per hour, then C.C. 5,000 ÷ 200 = 25 ft. extra radiation for each additional change of air.

A rule giving the relative pipe surface required for varying temperatures in ordinary back buildings, taking water temperature at 170 degs., inside temperature at 60 degs. and outside temperature at 30 degs. as unity. To be used in conjunction with the preceding rule.

Mr. Jones stated that in comparing the radiation given by various authorities for attaining the high temperatures required in drying-rooms the greatest possible variation in figures is found.

In giving a diagram (which cannot be reproduced here) plotted out with the rise in temperature to be expected with a given area of heating surface, when the outer air is at different temperatures, the results obtained are briefly these:—

The radiation reouired to give from 0 degs. to 45 degs. will give approximately from 10 degs. to 50 degs.
" " " 20 " 55 "
" " " 30 " 60 "
" " " 40 " 65 "
" " " 50 " 70 "
" " " 70 " 75 "

In other words, the radiation that will give a rise of 45 degs. from 0 deg. to 45 degs. will only afford 15 degs. rise from 60 degs. to 75 degs.

The question now naturally arises, why the heat ratios or multipliers for horticultural buildings should not apply to ordinary brick buildings, and why should the progressive ratio in the table for brick buildings differ so materially. Three reasons might be given, which would probably account for this:—

First.—The data or starting point differs; the conditions are also different; hence the ratios or calculations must be made to conform with the altered conditions.

Second.—The radiation required to give 60 degs inside, when 30 degs. outside, in ordinary buildings, is approximately 15 ft. super. per 1,000 cubic feet, and for glass buildings it is about 50 to 70 ft. super. per 1,000 cubic feet, or four times the amount to obtain the same temperature.

Third.—Mr. T. Box, in his excellent treatise on heat, gave what appeared to Mr. Jones to be conclusive evidence that the losses from large glass surfaces are proportionately less than for small glass surfaces, or about ·306 units of heat per square foot per degree per difference per hour for greenhouses, as against ·504 units for ordinary windows.

BY THE WAY.

The Japanese method of house construction is said to be to put on the roof as soon as necessary supports are in place, and afterwards build the lower part. Some of the modern skyscrapers are being built on this plan—the casing of the steel skeleton commencing at the top.

x x x

When an attempt was made to start the furnace in a church at Pelee Island, Ont., the other day, the apparatus would not work. Investigation revealed that during the summer a swarm of bees had taken up their abode in the chimney, and stored up therein so large a quantity of honey as to completely block the flue.

x x x

Apropos of the article in November issue of this Journal on the new Majestic Theatre, Toronto. A daily paper's report of a recent performance states that "the sensational fire scene and rescue brought down the curtain of the third act amid tremendous applause," I shall not be surprised if some day there should be a still more sensational fire scene which would not only bring down the curtain but also the building.

x x x

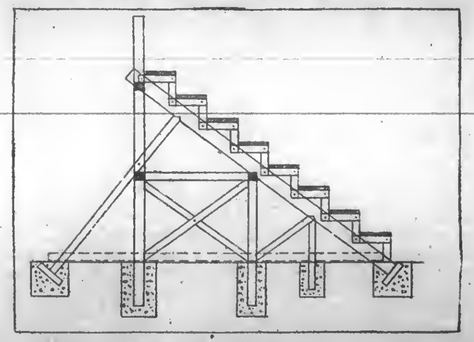
Two serious explosions of acetylene gas occurred in Western Ontario last month. In one instances a commercial building was wrecked, while the other resulted in the collapse of a church during the progress of an entertainment, and the serious injury of a number of persons, including the minister. It is quite time that the Insurance and building regulations were so amended as to compel acelylene gas generators to be installed in separate buildings at a safe distance from inhabietd structures.

x x x

A British Architectural Journal indignantly refutes the statement of Mr. Yerkes, manager of the London twopenny tube, that English workmen cannot build tall chimneys from the inside as is done by German bricklayers. In proof of the absurdity of the statement it declares: "German workmen are just as fat and heavy as our own, and require just as much scaffolding to hold them up; while, as for agility and intrepidity, we do not suppose any workmen surpass our own scaffold fixers."

PLAN FOR A GRAND STAND.

Attention has been called in these columns to several serious accidents which have resulted from the failure of heavily loaded grand stands. The proper construction of such stands should therefore be a subject of interest to architects and builders.



DESIGN FOR A GRAND STAND.

We reproduce herewith a sketch for a stand contributed by J. Barsley to an English publication. The uprights below ground level are proposed to be well tarred and set in concrete. The dotted lines indicate additional bearer if it is not proposed to fix the structure to the ground.

MATERIAL AND TECHNIQUE IN DESIGN.

By Prof. Percy E. Nobbs.

Note By The Author:—These three short papers (1) Drawing and Architecture; (2) The Styles of Architecture; (3) Material and Design; are intended as an introductioo to the study of Architecture for students assumed to possess no knowledge of the subject, and the themes are treated with regard to their bearing on study only. They were delivered at McGill University this September.

We have dealt thus far with the two great branches of architectural study (and by architectural study we must understand training in those things which lead up to the art of designing. In drawing we have the written side of our language; in building the living words with which the artist in stone and mortar speaks to his public. The idea of an artist without a public is, by the way, impossible: still there are wondrous few outside the architectural profession who understand. By the styles in the common acceptation, we must understand the traditional metric forms in which to string our poems; by style in the higher sense, we mean all that makes for character in work—good or bad. To-day it is with the proper structure of our architectural language that we have to deal,—that is the fundemental basis of design.

All modes of expression have one purpose—the conveyance of ideas from one man to another by means of the senses: and it is hardly necessary to add, true ideas. This power was not evolved that man might deceive his brother. The entire advance of man to the position we find him in to-day is based upon the acquisition of power to convey ideas to be accepted as true, or perhaps honest is a better word, for truth is after all a comparative affair—between the scientific truth of to-day and "the happy truth the careless angels know" there is a great gulf still fixed.

It will take us years of study to really appreciate this truthful quality in all great architecture, and it is only with a small side of this truthfulness that we have to do to-day, but it is necessary to understand something of this from the beginning of our studies in order to be on our guard against the lie in design. If we were simple XIII century craftsmen there would be no such need, but we are sophisticated XX century students, and the world is full of untruthful design, and when a lie is repeated often enough we are very apt to take it for gospel.

Now the particular type of lie we have to consider is the lie of material. The very basis of all design is knowledge of material (and the idea of material necessarily carries with it the process by which that material can be wrought—the technique, that is.) Of course before we design a thing we must thoroughly understand its purpose, but that is not the basis of design. That knowledge is shared equally at least by the client or the man who will use the thing, and there are men who know what is wanted to perfection, but who cannot design, and incidentally it is well for the professional designer that this is so (Mr. Kipling's "Story of Ung" contains the most brilliant exposition of this in our language). The state and form with which a designer invests an object depends at every turn upon the stuff it is made of and the way the workman will make it. There are other things than this in design, but this is the touchstone, the one essential.

THERE IS NO SUCH THING IN NATURE, NOR IN ARCHITECTURE (NOR IN ANY OTHER ART I THINK) AS ABSTRACT BEAUTY OF FORM, WITHOUT RELATION TO THE USE, MATERIAL AND STRUCTURE OF THE OBJECT.

The world of art has been mazed long enough among the unprofitable theories, about art appealing direct to the emotions and the glorification of the work of art for its own sake. We must have a good deal more than pure reason in anything that is designed before it becomes a work of art, but where that is lacking as a basis, the thing is fit for nothing but to be regarded as a more or less interesting exercise of skillful fingers.

We are all of us aware that building materials have differen characteristics without taking a scientific course on the subject. Stones are heavy and vary in size; Bricks are all of one size. Wood is obtainable in great lengths, cuts well, has strength of different kinds in different directions and shrinks. Steel has enormous strength in tension and considerable in compression. Wrought iron and cast iron have very different characteristics of strength and technique. Plaster is worked soft and set hard. Sheet metal bends. So with every material we can call to mind —we find differences in strength, texture and manipulation, all interdependent. This is what is meant when we speak of the genius of the material.

Truism No. 1—Some materials are more suited to certain purposes than others. We blush to indite anything so obvious, yet designers habitually ignore this fact or acknowledge it only by imitating in one material, another which they consider obviously the more suitable for the purpose.

Truism No. 2—Each material has its own process by which it may be reduced to serve a suitable purpose.—As obvious as No. 1 and yet mere frequently ignored in design.

Next year we shall go through a course on the techniques for all materials the architect comes in contact with,—stone, plaster, wrought iron, stained glass, mosaic and the rest, and our study will take the form of preparing detailed drawings, for the trades using these materials. This will be of great profit to us if we can draw well enough by that time. This by the way.

To reduce our present enquiry to a brief lecture hour we shall consider wood and stone only. There are hundreds of kinds of each, and every kind has its particular genius for beauty if used the right way, and a very important part of the designer's work is the study of woods and stones on this account.

It is to wood in general and stone in general that we shall confine our attention as an illustration of the axioms above laid down.

After stone has been broken into our service by such rough weapons as blasting powder, the pick and the hammer, it is reduced to shape by use of the point held in the mason's left hand and the mall or mallet wielded in his right. The stone is chipped or powdered away till the desired form is reached. This is the general process of reducing stone to our purposes and is illustrated happily on the coat of arms of Melrose Abbey in Scotland—it is a "canting coat" and may or may not contain the derivation of the name. In chief is a rose and below it a mell—thus happily symbolizing the delicate and intricate beauty of that wondrous Abbey and the mason's simple tools which wrought the fair plain ashlar and the moulded piers, the traceried windows and the crockets and bosses so "bellysh ycarven";—they are better carved nowhere.

In wood, we find in the grain and fibre a natural structure so different from that of stone that it is only rational to expect a totally different technique and a totally different kind of strength. Where the one breaks the other bends and tears. It will serve no useful purpose to work out the comparison here; we need only think of the two things to realize a thousand essential differences. The saw, the axe, the chisel, the plane, the fibrous chips and the long and curling ribbons, and above and beyond all the circumstance that wood shrinks and warps and if exposed to be wet and dry alternately rots, are all facts full of meaning which throng the mind when we bestow a thought upon the matter.

Obvious as all this is we must note it down and decide to keep it ever in view before submitting to be influenced by those same styles we considered last time, for in their study there lurk a hundred subtle temptations to us to forget those differences of materials.

"Let your wood be wood and your stone be stone," is the architect's application of the great yae aod nae commandment.

In pointing out a few local examples of this tendency to torget the natural way to treat materials it must not be supposed that this is a specially Canadian vice. It is as widespread as the tendency to pretend we are better than we know we are, and quite as futile.

Gothic window tracery as we find it in its fullest and finest development about 1500 A.D., is perhaps the purest one-material-evolved class of work within the realm of architecture. In the early XII Century churches narrow, lancet headed windows were used and in gables it soon became the practice to group these in twos, threes or fives, or even sevens side by side, as in the north transept at York Minster. The wall between each light was still kept the full thickness. The next step was to put circular windows over the heads of the range of lancet lights. The next development was the constructional arch to span the space occupied by all these lights as the wall was so much cut up. Then the space within the arch was made thinner than the rest of the wall, the lights come nearer together and the circular hole in the axpex of the arch gives way to such forms as trefoils or quatrefoils fitting more closely between the lancet heads. For ease in construction large slabs of stone 8 or 10 inches thick came to be used and these openings were pierced in them. This is plate tracery. As the construction became more skillful less and less of the plate was left, the piercings fitted closer into the spaces between the heads of the lights, etc., and real tracery is the result about 1250. Through the development of cusps and orders it is unnecessary here to go; enough has been said to prove the stony pedigree of the gothic window.

We have around us churches making more or less claim to be characterized as Gothic buildings and in a great many cases the tracery is of wood, reproducing to the best of its ability the forms which of right belong to stone and the "solecism" is none the less because such windows are painted to match the surrounding stonework. In matters of taste there is a right and a wrong as elsewhere, and anything sham about a building is as much to be reprehended as anything sham about an individual. When this sort of thing is done by way of embellishment to a place of worship the artifice seems peculiarly misplaced. Had such windows been frankly designed for wood construction no offence would have been there—they might or might not have been well designed; that is another matter. The reason why they were executed in wood was presumably economy or conceivably on climatic grounds. The reason why the shapes, sizes and design of stone windows was followed is that the building was to be "Gothic." The letter not the spirit of the law is here manifest, for the spirit of Gothic work is this above all things—Truth in construction, truth in materials and obvious, potent, exposed truth at that. That is the main reason why we shall study Gothic work here. It will habituate our minds to constructive and material honesty in design.

There are many kindred cases to the one above which meet our eyes in any modern town. It is wonderful how little of the ordinary common building that is done does not stand the test of this question of the material honesty.

We shall soon see in studying the evolution of architectural forms how great a part this translation of features from one material into another has played in the production of new forms when rightly done.

Forms originally evolved in wood may be translated to stone and vice versa with the happiest results, but they must not be wholesale imitations, with intent to deceive but rational adaptations.

The Greek Doric for instance was originally a wooden style of construction and the wooden forms still remain though they have lost all wooden meaning and appearance. Nothing that has been built has a more stony appearance than the Doric temple.

A case of the translation of stone to wood on the other hand is presented in Gothic screen work. We have seen how window tracery developed till it became the joy and glory of the church builders and the forms evolved within the mullioned window are found in screens, organ cases, wall panelling and stall canopies, but with very marked differences which make them perfectly suitable in their new places. The reduction of these stone forms in scale and their adaptation to wood construction and carvers' tools is what renders them at once right and beautiful.

A peculiarly futile type of hypocrisy manifests itself in such buildings as have different materials on their different fronts. Of course in city streets where buildings stand "cheek by jowl"; where the back is only the side of a light well—stone to the street and glazed brick to the back is obviously the best thing that can be done. It is usually the intensely respectable villa residence that is guilty of the enormity under consideration. Why so many corner houses should have stone fronts to a main street and brick fronts to side streets has never been clear to me. Nothing possessed of powers of locomotion and sight can be deceived by this depraved tradition (for it has become a tradition).

These sort of things pervade our modern surroundings and they will testify to our children's children of a great deal of hollowness and lack of ingenuousness in XIX and possibly in XX century life. We need not heap up examples. Once we set ourselves to seek for honest work it is extraordinary how much that is spurious and mean will assail the eyes. Where ignorance is bliss it may be folly, but it certainly is a duty to be wise.

To sum up these three opening lectures in a sentence—the study of these things which lead up to the art of designing may be enumerated in three words corresponding to these three lectures—Drawing, Old Work and Construction; by means of the first we study the second and thereby realize how truly the third may be said to be the fundamental basis of our art.

The new Cathedral in Liverpool will be built of red sandstone. The method advocated of determining the thickness of plate glass for windows to withstand wind pressure and vibration from traffic is to proportion the shearing section (the marginal or bearing length multiplied by the thickness) so as not to exceed the safe tensile strength.

NOTES.

The Architects' Registration Bill has been carefully revised, and the British Society of Architects will spare no effort to secure its passage.

Mr. Chas. Baillairge, who for many years has ably discharged the duties of City Engineer of Quebec, recently resigned the position, and is succeeded by his son, Mr. W. D. Baillairge.

Many new ceilings are whitened before they are quite dry, the result being that they have a smeary appearance when finished. Should there be any sign of moisture on a ceiling it is not in a proper condition to be whitened.

Prof. Capper, late of McGill University, Montreal, now professor of architecture at Owens College, Manchester, has given the first of a series of lectures at that institution on the work of the monastic orders in relation to architecture.

The fourth international conference for testing building material is to be held next year at St. Petersburg, Russia, in the month of August. Herr Fetmager, professor of the technical high school at Vienna, Austria, has been chosen president of the conference.

A course of six lectures will be given during the coming winter in the gallery of the Montreal Art Association. These will include an address by Mr. Edward Robinson, curator of the Boston Museum of Fine Arts, on Greek Sculpture, and by Dr. R. Tait Mackenzie, on Artistic Anatomy.

The late Viollett-le-Duc wrote that one of the most interesting examples of architecture in all France on account of its simplicity, perfect shape, and harmony of detail, was the Cathedral at Chartres. The north steeple of this unique piece of twelfth century architecture has lately shown signs of decay, but fortunately the Government architects have now taken in hand its restoration. The "old tower" of the cathedral, surmounted by an octagonal spire, is 350 feet high, being shorter than its sister (built in the sixteenth century by Jean de Beauce), but far more interesting.

The attention of Canadian architects and architectural students is directed to the advertisement appearing in the present number referring to the Annual Examinations of the R.I.B.A. It was a matter of regret that no Canadian candidates presented themselves for these examinations last year. It is hoped that a number will go up for examination in 1904. Any information required regarding these examinations will be cheerfully supplied by Mr. Andrew T. Taylor, F.R.I.B.A., 80 St. Francois Xavier st., Montreal, who is the representative in Canada of the Royal Institute of British Architects.

"The requirements of modern civilization are so varied and complex, and we live at such a rapid pace, that even the practice of architecture has been invaded by 'specialists' who apparently imagine that a thorough knowledge of technical details will compensate for a lack of knowledge of the art of their profession. There are hardly any modern pretenders so lacking in justification by their works as that of the architectural expert or specialist. It may be argued that this is the only scientific method of dealing with modern complicated requirements; if so, its scientific efficiency hardly justifies its artistic barrenness. My earnest advice to you is to make your practice cover as wide a field as possible; shun specialism, however lucrative it may appear."—Mr. J. S. Gibson.

A man whose business it is to sell sash ventilators claims to have made an interesting discovery the other day, says the New York Engineering Review. He was equipping an office, on about the fifteenth floor of one of the tall office buildings, where he found that his ingenuity could not succeed in drawing in any outside air. After spending considerable time and visiting the various floors he states that he found on the lower floors a very strong influx of outer air through the window, passing through the room, out of the transom above the door and into the hallway. There he says it was sucked up by the elevator, which is rather doubtful, because the elevator presumably sucks downward as well as upward. At all events, there was a strong current of upward air through the ventilator shafts and, there being no outlet at the top of the shaft, it found its way out through the windows of the offices on the higher floors. The effect therefore is that the occupants of those upper floors are breathing the discharged air from the lower floors. This is quite likely to be the case under many atmospheric conditions.

THE ONTARIO ASSOCIATION OF ARCHITECTS

Arrangements have been made for the annual convention, which will be held in Toronto on Tuesday, January 12th and Wednesday, January 13th, 1904.

Upon the afternoon of the first day an address will be given by Prof. R. C. Carpenter, of Cornell University, upon "Heating," a subject upon which he has written a book well-known as a standard volume.

On Wednesday morning, Prof. Percy E. Nobbs, A.R.I.B.A., of McGill University, Montreal, will give a paper upon "The Delineation of Architecture," and will give examples of various methods of rendering. It is hoped that a very full discussion will follow this address.

The Wednesday afternoon meeting will be addressed by Prof. J. Mavor, of Toronto University, on "Recent Developments in the Planning and Improvement of Cities in Europe and America" and Mr. Frederick G. Todd, of Montreal will, describe the "The Advantages of a Park System." The exhibition of architectural drawings will be opened on Tuesday evening and upon Wednesday evening there will be a banquet in the King Edward Hotel. It is expected that members of the Association from many places in Ontario will be present.

Mr. Henry Simpson, architect, has announced himself a candidate for the Board of Education of that city.

The carpenters' strike in Pretoria is over, and the men's demand for a standard wage of £6 19s per week of forty-eight hours has been agreed to.

CORRESPONDENCE

FOREIGN RECOGNITION OF CANADIAN SKILL.

DEC. 11TH, 1903.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—In your issue of November under the heading of "Foreign Recognition of Canadian Skill" you refer to a Canadian artist receiving several commissions for memorial windows from the United States—and express astonishment at the fact that "an order amounting to about $10,000.00 for memorial windows to be placed in a church in Montreal was given to a U.S. firm" and that the duty of 30% paid on these windows was afterwards refunded by the Government; and your article suggested that "an explanation should be demanded of the Canadian Minister of Customs."

Apropos of this the writer wishes to say that very little blame can be attached to the Minister of Customs; (the Hon. Mr. Patterson,) although the facts are as you state. The Minister was interviewed and the facts as he gave them are, that for many years back, previous to the present Liberal administration, this custom had been followed, and by special Order-in-Council the duty was refunded, and it was difficult to draw the line without apparent discrimination to the particular ecclesiastical body that made the application. And further that the application for the refund of duty required had always been accompanied by a sworn declaration that it was impossible to execute this work in Canada. Let us hope that the ecclesiastics, on the supporters of religion, sinned in ignorance.

The Minister promised, and we believe he has carried out his promise, that this should cease. No fault can be found if the work should happen to have been that of a professional artist, such as Mr. Holiday, Frank Brangyn, Mr. Richardson, and others,—but these refunds were asked for and given on purely "commercial work," that is to say—work where the identity of the artist was sunk in the firm carrying out the order. Productions executed by artists of the "status" of these gentlemen would only benefit the taste for good productions in stained glass, and rightly so, might be admitted free, but all of the work carried out by "commercial stained glass firms" either in the United States, England, the Continent—the price being equally good, could be executed here.

Before concluding the writer would like to add that a prominent protectionist in Montreal, a gentleman who is about to seek the suffrage of the "electorate" with the purpose of imposing upon the people of Canada a high protective tariff was largely instrumental in placing the above order referred to in the United States.

This, I think, Mr. Editor should illustrate the insincerity of the "protectionists" who are "free-traders" for themselves, but "protectionists" when "others" are the purchasers.

Trusting this explanation will clear the present Minister of the blame your article imposes upon him.

I beg to remain,

Yours very truly,

"VERITAS."

VENTILATING SYSTEMS.

TORONTO, December 4, 1903.

To the Editor of the CANADIAN ARCHITECT AND BUILDER:

SIR,—I note a letter in your November issue, calling attention to the ventilation of the McIntyre Building at Winnipeg. The writer of the letter invites criticism and states that a discussion on the subject might be interesting and instructive. I quite agree with him on that point, but believe that the discussion should be on the ventilation of this building in particular, rather than on the system in general.

In order to discuss it intelligently it would be necessary for us to know the size of the building, its sub-divisions, the nature of business carried on, apartments and the number of occupants, the size of the vent shafts and the openings into the different apartments, together with their location. What provision is made for the admission of fresh air and have we to depend on gravity alone for the draft in the flues, or is artificial means provided?

We would also have to agree on a definition of ventilation which I understand to be the admission of fresh air in sufficient quantities to diffuse, dispel or drive out all vitiated air, or air containing more than from two to four parts of carbonic acid, in 10,000 parts, the air to be taken from a reliable source and to be distributed in desired quantities throughout the different apartments, according to their requirements; the entire system to be positive in its action and under the control of the operator.

In taking this matter up I think it would be well to have an approximate estimate of what the installation of this system cost; we would then be in a position to make a comparison of the costs of the various systems. My own opinion is that a mechanical device could be installed for a little over the cost of gravity ventilation, while the cost of operation would be very small if you take the results into consideration.

I take this matter up as I am interested in ventilation and I would be very glad to see a general discussion upon this question.

Respectfully yours,

VENTILATION.

NORTHWEST LETTER.

WINNIPEG December 14, 1902.

Although the winter has now thoroughly taken hold of this country and the thermometer has already registered as much as 25 degrees below zero on several occasions, building operations have by no means come to a standstill. It is most satisfactory to note this, for at no distant date it was universally considered, and is so yet by those not acquainted with the actual conditions, that for a period of some four months duration building of all description was compelled to cease. Work is now progressing in all trades and although the severe weather makes the cost much in excess of normal prices, on account of heating, etc., required, the cold weather does not prohibit the carrying out of good work. If these points were more widely advertised it would dispel the illusion many people hold, that because the thermometer at times registers as much as 40 below zero, work of all kinds must be suspended for the whole of the winter. This belief is held more particularly by those in the "Old Country," and if these facts could be brought to their notice it would help materially in encouraging good mechanics to immigrate to these western provinces. A present difficulty in building, on account of the great amount of work in hand, is the scarcity of skilled labor and much work has been hampered this year for this reason. The enormous amount of building, compared with former years, and the lack of labor will necessitate, for the completion of same to be realized before spring, the carrying on of the work throughout the winter months, and although it may be a loss to contractors in many cases, it will benefit the country at large, in that it will not only give continuous employment to the trades but it will more establish the truth and destroy the fallacy regarding building in winter.

The carpenters' strike which took place late in the summer retarded work to some extent. The disturbance was the usual several complaints of the Union, viz: a nine hour day from seven to five, a minimum wage of 35 cents and the recognition of the Union. No prolonged lockout took place and in a number of cases the employers agreed to the demands of the Union immediately upon receiving a notification specifying their requests. In some instances the men were out several weeks, but these cases were rare. Some seventy-five, more or less, masters have up to date agreed upon several points demanded by the Union, which agreement holds both parties for one year. The employers who refused to submit to the demands number about fifteen and include some of the large firms of the city. As no association of master carpenters exists in Winnipeg, the difficulty found by the Union was that each contractor had to be notified individually and each acted according to his own judgment. The advisability of setting the minimum wage at 35 cents appears on looking into the matter to be questionable. Taking a nine hour day with eight hours Saturday at 35 cents, gives a weekly wage of $18.55. This amount for a minimum appeals to one as rather high. There must be many instances in the carpentering trade where rough work is done, especially in a growing country such as this, where the labor cannot possibly be worth that amount. Many men there are who are worth no more than say 30 cents but who can perform this rough class of work as well as a thoroughly experienced man. It would be different if work was scarce and labor plentiful and where the good men would be frequently discharged in favor of the cheaper ones, but this is not the case. When such time arrives then the Union can protect the best mechanics but in the meantime the contractor or public must pay the price and consequently building becomes more expensive and the class of work stands still.

The subject of trade unions brings to one's mind the desirability of a "union" among architects. Not on the lines of protecting themselves as is the case of the trades, but for the protection of the public and the advancement of the art. On this theme I should like to bring to your notice some points that have impressed me as illustrating the great need of such an association to be formed in Winnipeg. Things in the profession are at present being carried on in a very loose way. Some years ago the resident architects in the province submitted a bill to the local Legislature petitioning them to grant a charter to an association formed of resident architects empowering them to prevent any outside architect practising without first becoming members of the provincial association and thus making it a close profession. This idea of "union" is not of a very high order as it was apparently one meant, I am given to understand, not to further the interests of the profession but only to act as a barrier against outside men from entering the province. What is needed is an association formed on the basis of the Ontario Association or other similar body with the direct object of raising the standard of architects and of work done. This can only be accomplished by educating students of the rising generation by the help of the Association and by making it compulsory to pass certain examinations before being allowed to qualify as architects. This might be done by an association being formed and a bill being authorized which would make it necessary for such qualifying examinations to be passed before one would be allowed to practice and for the measure to take effect say five years from the date of the introduction of same. This procedure has of course been ineffectually placed before the Ontario House on several occasions but Quebec has been more fortunate and Manitoba might do likewise. The present manner of practising architecture necessarily reduces work to the very lowest standard and it seems an injustice to the public that any man on the street can, when the whim takes him or when a prospective job looms up, place the word Architect after his name and publicly practice as such. It would be most unfair to cause those who were not architecturally educated to a specified level to cease from practising the profession, but it would be most just to compel those who were not competent from the public safety standpoint, to withdraw the designation "architect" from their names. The free use of the word by such a nondescript class has become such that in some cases, with a certain public, it is simply synonymous with "Jerry Builder." This does not exaggerate the prevailing practice in any way or form, and in fact one would hardly dare to describe the exact condition of affairs in this direction. The course now open is, for those architects who feel that the exigencies of the case demands it, and regard the profession as one worthy of protection and who can realize the effect of the continuous practice as now prevalent, to join in forming an Association as above for the repression of a system that can do nothing but lower the status of all concerned.

Taking leave of "Unions"—the city of Winnipeg tax papers are now being presented and show a rate of 21.50 mills made up as follows: schools 4.38, municipal commissioners .23, public parks .50, municipal expediture 16.39. Total amount of taxes levied $779,878.10 on an assessment of $36,264,920. To keep the rate of 21.50 mills throughout the "business tax," is arrived at in a strange manner. It is done by multiplying the actual annual rental by four or five so that although the rate is really 95.50 mills it reduces it to the 21.50 mills required. The tenant of an office or a shop having a rental of say $1000 pays $91.50 on shop or office. This business tax is of course in addition to the regular tax of 21.50 mills on the assessed value of the building and land. It is hard to obtain information as to the reason of this apparent extortion, but of course there is a reason, and that is supposed to be sufficient information for the taxpayer. To carry on the administration of the city's wants it requires that the amount of money expended must be paid, but the equity of proportioning the taxes in this manner looks on the face of it doubtful.

The prospects of building for 1904 look very cheerful. Although the total amount of building permits issued in 1903 aggregated to something like $6,000,000 the feeling at present is that this amount will probably be doubled next year. The C.P.R. improvements, the agreement of which has now been finally signed by the city, will entail an expenditure of something like $2,500,000. The whole of this project may not be proceeded with next year but the building of the subway is definitely settled.

MANITOBAN.

A SUGGESTION.

Toronto has recently rounded out her suburban park system by the purchase from the Dominion Government of the garrison common extending

FIG. 1.

along the lake shore to the exhibition grounds. When improved this will form a combined park and driveway unsurpassed probably by any on this continent. The city is still in urgent need of one or more squares in the business district. The Council having decided that the proposed new Public Library building shall be located down town, the opportunity is afforded of placing it in the centre of a public square convenient to the business district. In order that the building may form one of the prominent architectural features of the city, and be well lighted, it should have an ample site. Why not as it were kill two birds with the one stone, by purchasing a site which would add to the appearance of the library building and of sufficient area to meet the requirements of a public square? The opportunity should not be missed of thus accomplishing both objects at a minimum cost.

FIG. 2.

TESTED FIREPROOFING.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—A publication in Chicago which represents the Tile Manufactures, has been making a record for itself in attempting to belittle all other forms of fireproofing and is especially bitter in condemnation of concrete as a fireproofing material. They make use of some mishaps during construction, to argue that concrete is unreliable and lacks strength as a fireproofing material.

A great many accidents have happened to brick or terra cotta blocks, but that does not condemn their use in buildings.

After all the real test of fireproof construction and the test upon which one can form a correct judgment is an actual fire in a building, and from the effect of such a fire upon the materials used one can judge as to whether the construction is reliable or not.

We propose to print cuts showing the effects of fires in a number of buildings, some of them where terra cotta was used as a fireproof material and some buildings where the concrete system was adopted.

Illustration 1 shows the Horne building in Pittsburg, Pa., where the fire burnt out the woodwork and contents, but was not hot enough to destroy the stonework on the front; it was hot enough to destroy the terra cotta floors throughout a great part of the building, necessitating rebuilding of all the floors.

Illustration 2 it is a case where a small fire occurred in a pipe shaft in the Old Colony Building, Chicago. There was supposed to be nothing combustible in the shaft, but there was some pipe covering and some pieces of board and these caught fire. Even with this small confined fire, the heat was sufficient to displace the terra cotta partition, adjoining the shaft.

In another issue we will illustrate some cases of fire in buildings where concrete systems were used.

F. W. BARRETT,
Manager Expanded Metal Co., Toronto.

BUSINESS NOTES.

Architects and others should be interested in the announcement in this number of Messrs. Sheldon & Sheldon, of Galt, Ont. It has reference to their hot blast system of heating for schools, hospitals and other public buildiogs, factories, etc. They are successors to the McEachren Heating and Ventilating Co. and have had a long experience in this line. Particulars regarding their method of heating will be furnished any reader who will drop them a post card mentioning this journal.

EXAMINATION TO QUALIFY FOR ASSOCIATESHIP
—IN THE—
ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The Royal Institute of British Architects desiring to give facilities for those in the Colonies to qualify by examination for associateship in the R.I.B.A., will hold the fourth examination from June 14th to July 1st, 1904, in Montreal. Applications, fees and probationary work must reach London by the first mail arriving after April 9th, 1904 Intending candidates who must be not less than 25 years of age, can obtain application forms and copies of the previous examinations on application to

ANDREW T. TAYLOR,
Hon. Sec. R. I. B. A. for Canada,
North British & Mercantile Building,
80 St. Francois Xavier St., Montreal

All who are full members of the Province of Quebec Association of Architects and the Ontario Association of Architects by examination, are exempt from probationary work.

Students' Competition.

A large number of students have submitted designs in the competition for a public library building announced in our November issue. The merits of these designs will be considered by a committee appointed for the purpose by the O.A.A. and the Toronto Architectural Eighteen Club, whose criticisms and award we hope to publish in our February number.

Ontario Association of Architects.

We are only able in the present number to make brief mention of the annual convention of the O.A.A. held in Toronto on the 12th and 13th inst. Next month we hope to publish a more extended account of the proceedings, which were of a very interesting and instructive character. The excellence of the papers may be judged by the one by Prof. R. C. Carpenter, printed in this number. The address of the President, Mr. W. L. Symons, while comprehensive in its scope, dealt at most length with means whereby friction between employers and employees in the building trades might be lessened and strikes avoided. The suggestion was again made that the annual conventions should be held alternately in the leading cities of Ontario. The difficulty experienced in securing a large attendance even in Toronto offers little encouragement to make trial of the idea, which if found feasible, would be likely to widen interest in the Association and its work. The exhibition of drawings and photographs contributed by architects in all parts of Canada added greatly to the interest of the occasion. In common with our readers we are indebted to Prof. Nobbs, of McGill University, for the notes on this exhibition appearing in another column. The proceedings terminated with an enjoyable dinner at the King Edward Hotel, at which several interesting addresses were delivered by Mr. W. E. Doran, of the Province of Quebec Association of Architects, Prof. Mavor, of Toronto University, Prof. Nobbs and others.

Decorating and Furnishing.

As a natural accompaniment to the rapid increase in wealth in Canada during the last decade has come a larger expenditure on buildings for domestic use. This is particularly true as regards the interior decoration and furnishing of the house. In view of its growing importance the present number is specially devoted to decoration and furnishing. Our illustration pages show some interesting examples, while the specially written articles by well known authorities treating of various phases of the subject should add to the knowledge already possessed by our readers.

TENDENCIES OF WALL PAPER DESIGN.

French Chimney Top.

Before attempting to outline the tendencies of wall paper design at the present time I should like to earnestly direct the attention of architects especially to a kindred subject, one at least inseparably connected with the decorator's work. I think I can say without exaggeration that decorators approach the work of covering the plaster walls of houses and other buildings erected of late years with trepidation amounting almost to terror as to the results. To see one's best laid plans and most cherished schemes completely frustrated by the treacherous under surface is more than disappointing. The "skin or putty coat" so much in use to impart that beautiful snowy smooth surface which so strongly appeals to some people has usually no actual adhesion to the coat beneath it and only waits the application of some material to sever its very weak connection and destroy the decorator's work. The so-called sand finish of many plasterers is almost as great a delusion. On walls thus treated many patches will be found into which no sand and very little plaster of Paris has entered—nothing but lime. Plasterers freely admit these imperfections and also that it is possible to get as good results as were obtained in houses a generation ago but they claim that current prices do not admit of the use of sufficient plaster nor of sufficient time being given to the work. Surely it is a false economy to cheapen a material which is admittedly imperfect at best, which covers so much surface and which places a stamp of dilapidation on the house out of all proportion to its relative cost to the total cost of the building. I feel satisfied that this work does not receive the attention it deserves at the hands of the architect, and that not only would the problem of decoration be greatly simplified but that the life of the plastering would be materially lengthened if honest work were insisted upon.

Another feature in the preparatory work of ceilings and walls for decoration deserves more than passing notice. I refer to the obtaining of true perpendicular and horizontal lines in the angles of the room. It is no uncommon thing to see the ceiling run from one to one and one half inches out of true in a wall of twelve or fifteen feet. The upright angles of the room are frequently as much out and in many cases meander in and out of line as they climb to the ceiling. Many rooms are two or three inches wider at one end than at the other. It can be easily understood how difficult it becomes under these circumstances to apply pattern of any sort so that it shall not appear to be leaning one way or the other. These defects are not by any means confined to cheap buildings but may be seen in some of our most pretentious structures. In almost every other trade if the work proves defective in itself it has to be made good. Why should not a guarantee be required from the contractor for plastering that his work shall successfully meet the demands made upon it in the decoration which may subsequently be applied to it?

And while I am on this portion of my subject I should like to point out what is always to the decorator at least the unexplainable practice of many architects, of carrying doors and windows in the room to two, three or more different heights. My own dining room has five such openings and every one is of a different height, varying from the others by several inches. There was no reason why the three doors at least should not have been of the same height.

The foregoing are some of the difficulties in the path of the decorator, whose remedy lies in the province of the architect. And their connection with my subject is in this. When the standard of design and the value of materials in wall coverings have advanced as they have done of late years it becomes increasingly necessary that the remedy should be applied and more perfect results obtained. The various canvasses, burlaps, denims, buckrams, etc., now manufactured solely for decorative purposes are undoubtedly great acquisitions to the resources of the decorator and are all perfectly practical on properly plastered walls. But the risk and labour of applying them to the ordinary conglomeration of sand, lime and plaster is so great as to greatly restrict their use.

Pattern has been sparingly applied to these materials partly because their own texture and coloring is quite satisfying and partly because the ordinary printing process necessitates too frequent repetition and the consequent wall-papery appearance. Block or hand printing has not been so used to any great extent though I can see no reason why excellent results might not be obtained by block printing or stencilling.

Book cloths, that is cloths used in book binding, the process of manufacture being slightly altered to adapt them to the purposes of wall covering, are sold under the trade name of Holliston cloths. The dyed burlaps and denims are too well known to need description. A Japanese material called grass-cloth woven of raw flax and dyed in beautiful tones has all the appearance of raw silk on the wall. It comes in rolls of eight yards, thirty-six inches wide. A plain paper of English manufacture called silk fibre comes in a variety of excellent colorings and has a texture much superior to the ordinary ingrain papers. These various plain materials form an important group showing a tendency to return to plain wall surfaces but with the relief of texture of one sort or another. They also call for something in the nature of a frieze to relieve the absolute plainness of the wall and although the frieze in wall paper has not yet reappeared among us, the demand has been met in England in the work of two or three men, notably Bailie Scott and Shand Kydd, the latter of whom has produced some very beautiful friezes both in design and coloring, quite individual in character and which are being extensively appropriated by other designers. On account of the amount of hand treatment in them they are themselves rather expensive. In actual progress the English designers are undoubtedly to the front. Much attention is being given in their work to the purpose for which the material is to be used. Many of the designs therefore are flat stencil effects in two tones of one color. Where varied color is used, green and blues are laid together, or greens, blues and purples, or again browns, greens and yellows, giving a pleasing relief to the eye while preserving the flat wall surface. The German designers have worked on these lines as well and their color is good but their designs are much in the extreme "new style"—so extreme, indeed, that to an ordinary mortal they are anything but beautiful. To add to their undesirability they are easily copied and have been widely copied by American manufacturers, and as is usual in such cases, the glaring faults have been accentuated under the mistaken impression that they formed the main attractiveness of the designs. The English designs are not so much in favor with the great American public and are thus saved this degradation.

To what are known as the sample-book houses and the departmental stores is due much of the cheapening of design and materials in wallpaper as in so many other lines. Something with a semblance of merit but spiced up with touches of color to catch the popular taste has to be provided at a price which will insure large sales. Thus it becomes increasingly difficult year by year to purchase designs sufficiently distinct from these meretricious vamped up piracies. Apparently the only safe course is to confine oneself to flat quiet effects in two or three tones of analogous colors and yet there are some glorious walls to be had in strong color from the collections of the leading British makers.

The French designers adhere pretty closely to their traditions in the direction of marvellous reproductions of the effect of silk, leather, tapestry, &c. As I pointed out in a former paper there is no pretense in these creations, that they are the actual material themselves, and it is therefore prefectly legitimate in such an intrinsically valueless material as wallpaper to produce any effect that will make a good wall. No objections of this sort, however, can be raised against the beautiful flocks or velvet papers in which the French excel and which have come in with the new styles or revived styles in architecture. Nothing can quite take their place in the white and gold rooms of the Empire or the Colonial of New England and Virginia.

Of the best American lines it can only be said that they are good in so far as they so closely follow the European makers as to be almost indistinguishable from them except to the trade expert. When originality is attempted it is not of an order to commend itself to a cultured taste. The craze for much display at little cost has controlled the output of a majority of the American factories.

Our own manufacturers have not yet reached a stage where the designing and coloring of their wallpapers can be seriously considered from an artistic standpoint. This condition of affairs is likely to continue for some time to come, those wishing really good design and coloring being ready to pay the difference in price for the imported lines. It is gratifying, however, to note that even in the domestic lines the showy pressed, embossed gilts, glimmers, and other such abominations have disappeared.

Some curious revivals come upon the market at times and enjoy a short run of popularity out of all proportion to their merit. An old house in Boston was pulled down the other day and on the walls of one room was exposed a panel treatment in old Chinese hand painting on small square silk sheets, the subjects reminding one of the old tea chest pictures. At once there was a demand for subjects of this sort and an enterprising importer engaged Japanese artists to produce hand painted wall hangings fifty yards long without repeat by any required width up to five or six feet. The painting was done on fine muslin with a backing of strong thin paper. Of course this revival of Japanese design is merely a fad and yet it indicates how keen is the pursuit of novelty in the decorating field.

W. H. Elliott.

PLANTS IN DECORATION.

By C. Mangold.

Who can imagine decorative art without plants? or estimate what it owes to the vast resources of the vegetable kingdom? They are so inexhaustible and so varied that they must always be its chief inspiration, and yet it has made only a very restricted choice from the wealth at its disposal. Why is this, and why at different periods have artists resorted to different plants, and why in some cases have plant-forms consituted the main feature of a design and in others played merely a subordinate part?

Te be available for decorative work a plant must not be too small, and must have a charateristic growth or a lively colour. In the earliest art-epochs of any country those plants naturally appear in decoration which are indigenous to the country, and the palm tree is thus the first plant we know to have been used, lending itself readily to the purpose, and being a native of the land which has given us the earliest examples of decoration. An artist must be familiar with the appearance and life of the plants he uses in his art, and this is only possible in the case of plants which are constantly before his eyes.

The size of a plant and its separate parts is of importance, because there are artistic limits to the representation of very small plants on a scale larger than that of nature.

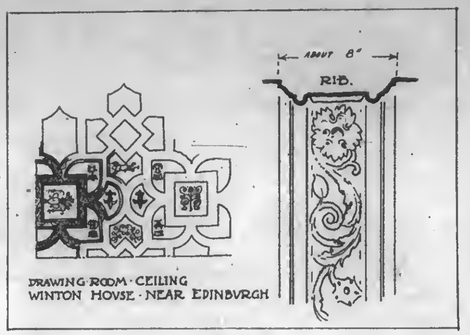
The durability of a plant is not without its weight. Not only should portions of it keep unwithered long enough to be copied, but also to make wreaths and other natural decorations. These, too, can be copied, and have at all times furnished important motives to decorative artists. In the time of the Renaissance, the use of natural floral decorations and wreaths were even commoner than now. The Italians in particular are greatly addicted to this form of decoration, and possess a large number of different evergreen plants suitable for the purpose, such as the laurel, the evergreen oak, the olive, the myrtle, and the cypress.

The choice of plants for decoration depends on the character of the nation at the time, and the fashion is always changing. We see that well in the flower representations of the present day. The vast demand for such designs for carpets, wallpapers and womens' clothes, has caused the artist to seek for inspiration from a very much greater number of plants than he has ever done before.

In many cases it is still possible to point out the particular plant from which the artist has taken his motive, but it is much more common to see fancy plants in which the mixing of types has been carried so far that the origin of the separate parts cannot be distinguished. Decorative art is, in fact, freeing itself from the trammels of precedent and striking out a new path for itself. This is as it should be, and the artist must go to nature for his novelties.—Maler Zeitung.

PLASTER DECORATION—MODELLED AND HANDWROUGHT.

Before considering a special method for the artistic treatment of a material it is as well to come to some definite conclusion as to what may be called its "genius." By the "genius of the material" we mean the characteristic kind of beauty which it possesses per se, without taking into account even the technique —the treatment which is least calculated to diminish



No. 1.

this beauty is the best. In the case of a mantlepiece of highly veined marble every member of moulding added is so much waste labour and in bad taste, for the flat or gently waved surface is alone compatible with a full realization of the beauties of the material. In white marble, on the other hand, the most delicate moulded surface will tell, and the texture of the material, too, suggests clean-cut decisive forms—the semi-transparency and light absorbing quality of white marble requires a definition of actual form which when cast in plaster appears coarse as compared with the original.

Plaster is as white as marble, but, lacking transparency, we find lights reflected into shadows and vice versa in a way no other material can rival. The most delicate or rather the softest (for delicate is apt to suggest smallness of scale) modelling will therefore produce considerable emphasis, while extreme sharpness or undercutting will show violent contrasts wholly destructive of this tender genius of white plaster. Mr. E. S. Prior has said "Plaster is the most impressionable of all materials which give architectural surface. Its response to the hand of the craftsman is sympathetic and immediate. It has not to be chiselled like stone or wood or have ideas hammered out of it like iron: a touch of the finger gives it life." Thus both the material and the technique suggest a tender treatment. We are here impelled to lodge a word of protest against the practice of painting plasterwork any colour but white and preferably lime white. To paint a cornice chocolate and pick out enrichments in gold is at once to stultify the purpose of plaster and ruin all the beauty of texture with which it is naturally so highly endowed—Where are the lights and shadows fled?

Now, considering the beginning of plaster work in England under "bluff King Hal," it was we find to Italian craftsmen that the earlier works must be attributed, but a characteristically English school soon developed. It is worth noting that much of this XVI Century work is far more plastery than what came later, though it is only within the last century that this trade has really fallen from its high place among the arts. And realizing this, there is a considerable movement among architects at home to lead the plasterer once more above the commonplaces of enriched stucco mouldings with mutules, consoles, dentils, egg and dart and all the rest of the sharp edged truck with which many a modern classic building is besmeared.

The type of these earlier ceilings is shown in our illustration from Wintoun House—the rib with moulded edges and enriched soffit divides the ceiling into geometrical panels in which occur a collection of ornamental motives of all sorts— heraldic devices, masks of mythical kings, conventional floral designs, initials, etc.

This type gradually gave place to the more formal corniced and coffered arrangements with the great circular garlands in which Inigo Jones and Wren delighted. In the earlier work the mouldings are more true to the "genius of the material," while in the later efforts the modelling reaches a very high standard though over inclined to naturalism.

In your Elizabethan ceiling the rib enrichment is usually cast, some running pattern of vine "with bunch and berry and flower through and through," while as often as not the panel motives are modelled "in situ." In the Georgian work also the great garlands are very often hand wrought "in situ." It is in the intervening debased period (and there is a world of inspiration in the work of debased periods) that we find a technique in vogue which combines the cast with

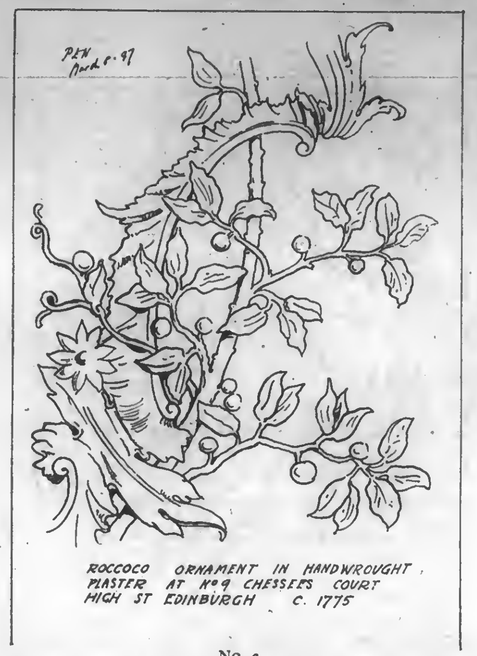
No. 2.

the hand wrought methods and which has this to commend it to a commercial age, that no other kind of ceiling decoration will give so fine an effect for a given outlay of skill and labor.

Before considering the mixed process which is our subject, a few words on the relative advantages of hand wrought and cast work may be of use.

It is the great advantage of hand wrought work that it can be done "in situ." Lighting is an all important question in plaster modelling, while the only way to

get a decoration the right size is to execute it in its place. To execute hand wrought plaster in the shop and then fix it is a very futile proceeding. In hand-wrought work we get the additional value which attaches to the unique. Though a good thing wil stand repetition while a bad thing is none the better for



ROCOCO ORNAMENT IN HANDWROUGHT PLASTER AT N°9 CHESSES COURT HIGH ST EDINBURGH C. 1775

No. 3.

being the only case in point, still it is nicer not to have the stereotyped ornament we know exists in the shop round the corner and in the house where we dined last night, right in our own parlor. Moreover in hand-wrought work balance takes the place of repetition and between the value of balance as an ornamental basis and repetition there is a great gulf.

Handwrought work can never be so perfect as cast work owing firstly to the speed with which it has to be modelled while the material is setting, and secondly to the impossibility of using wood tools or fingers. To the former the lime or cement adheres while the latter are burnt. The use of metal tools is the reason why one does not see modern handwrought plaster with a truly modelled surface; it looks like sketchy carving. The men of old time used to slake their lime for years and mix it with all manner of strange ingredients to render it plastic and slow, and we can only regret that this is not now commercially possible.

Now the dreary monotony of themes of plaster decoration depending on quantities of cast detail is patent to all who give the matter a thought, though for enrichments of the right sort and running repeats, etc., casting can never be dispensed with.

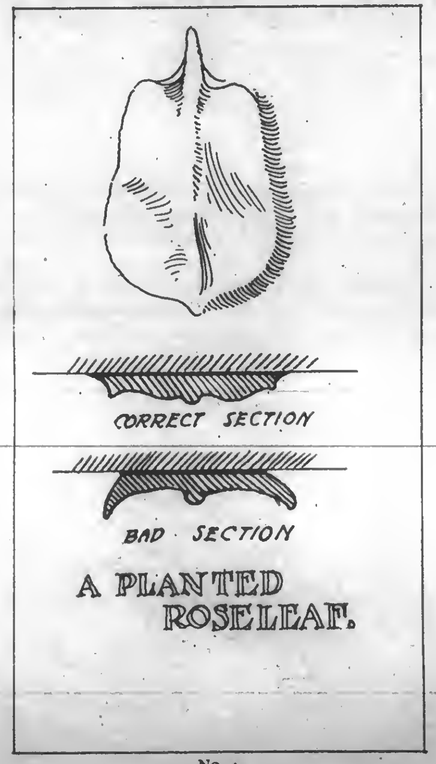
From the above we think it might be inferred that an ideal kind of floral plaster decoration would consist in having parts modelled in clay and cast and parts modelled in situ, thus ensuring a delicacy in the leaf, flower and fruit work while admitting of the utmost freedom of arrangement and stem modelling with regard to lighting and variation. Such a process we find in use in the latter half of the XVI century, and it seems quite to have fallen out of favor till some domestic architects at home by making measured drawings of old plaster work discovered that leaves and fruits supposed to be hand modelled were all of a pattern, a fact that would never be guessed from the ground, because each leaf taking its light at a different angle presents a different aspect. This little deception is the only "trick" in the particular branch of the trade.

This method lends itself particularly to the covering of large surfaces such as ceilings; coves or domes with a varied enrichment of surface, breadth being well assured by the family resemblance of the items modelled and cast, while any degree of richness can be attained by a closer or wider spacing of parts.

I have seen a vine treated happily enough with only one type of bunch and leaf, but in my own experience several types varied in size have been used.

It is worth while to note what the section of plaster leaves should be with regard to the surface of the ceiling or cove. The illustration shows this and I need only say that the section advocated will make the ornament look a part of the ceiling, not something to be knocked off.

Now to describe the process of doing a ceiling



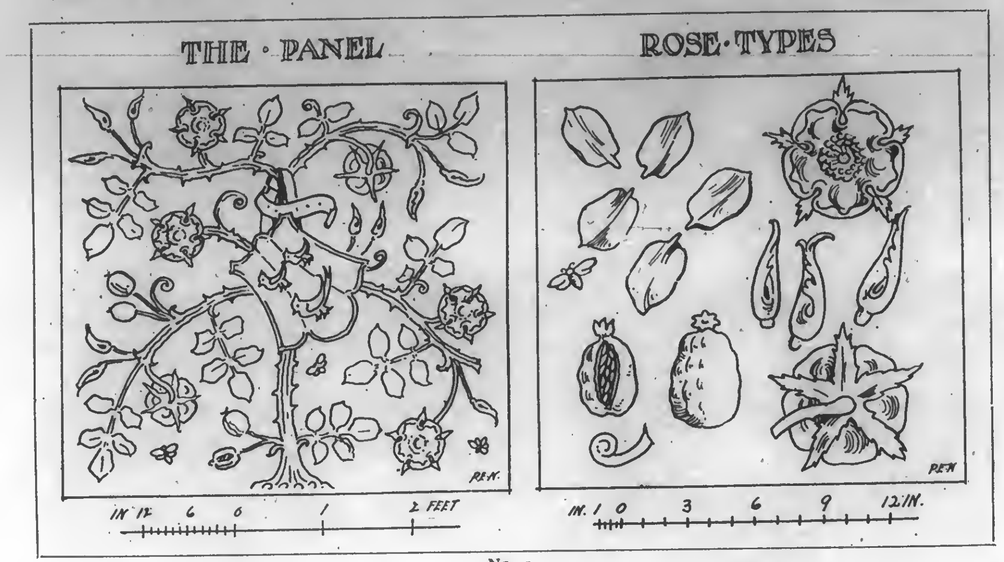
No. 4.

in this way. Let us suppose our types or items have been modelled, and the number of each that will be wanted having been calculated, they are cast and ready in baskets. They may be for vine, or rose, or lily, or oak, or maple; they may be stiffly conventional, severely correct to some recognized style or free to the verge of naturalism. In a word they may be as their designer

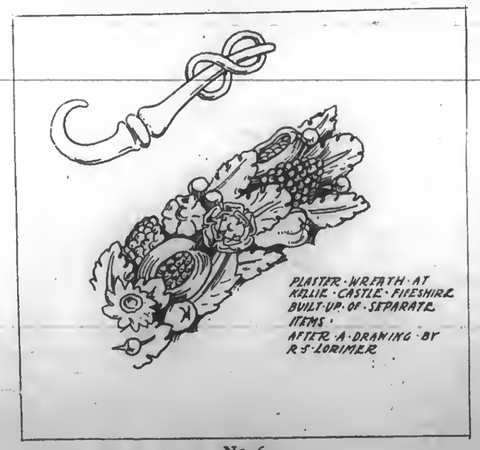
fancies. Next the scaffold is mounted and the dispositions set out in blue pencil on the plaster. Stems, wreaths, ribbands to be hand wrought being carefully thought out, while the positions for leaves, fruits, shields, or inset subject panels may be marked and numbered.

In disposing the stems care should be taken to avoid great curves and violently assertive scrolls, as this type of decoration aims rather at enriching surface in a subordinate spirit than at distracting the attention, and there is nothing like a strong bold curve for catching the eye.

The modeller then goes up and fixes his leaves and flowers, breaking the ground to form a key, and flushing up smoothly round the edges with his Parian Cement,



No. 5.



No. 6.

in which material slowed down with lime, he will also execute the stems, &c. Give him a bit of vine branch or a thorny rose stem and try for a good conventionalization of it. The twist of the vine and the thorns of the briar are easy characteristics to grasp.

When subject ornament is cast on the flat for insertion it is well to run a bead round the joint or to recess the plate in the ceiling. Plaster of paris and lime are not quite homogeneous in texture and the joint on a flat side-lit surface will show unpleasantly unless frankly acknowledged.

In making up the great circular garlands so characteristic of English XVII century work a process analagous to the above was often used. Berries and fruits are attached with string to nails driven into the hollow bed while soft, larger fruit and leaves being pegged or merely cemented on. In garlands so made up there is often a certain crudeness of composition, but they are far more likely to be rightly conceived as to scale and proportion than when the garland is cast in lengths to repeat while this last attribute is happily lacking. Compared with garlands hand wrought, in parian cement, these have the advantage already pointed out of lacking the carved out and sketchy feeling natural to quick modelling in a hard setting medium.

As an example we publish a design for a small coved ceiling with details and notes which may be of interest as an attempt to revive old methods.

To sum up the advantage of this old method of plaster decoration, we have seen that the amount of highly skilled modelling required is not very great. Half a dozen types will do for a large job. The stem modelling can be easily taught an intelligent workman. Any degree of conventionality or naturalism can be obtained which is desired and also any degree of richness or simplicity. The decorations are designed "in situ," an advantage quite as important as their being so executed.

With regard to plaster ceilings in general we would say that this is preeminently one of the cases where restful enrichment is called for and it is time we ceased securing this by the employment of forms which only fail to distract on account of their wearysome familiarity or conspicuous lack of beauty. Nothing in a ceiling should assert itself at the expense of objects on the walls or the furniture, but a ceiling need not on that account be wholly dull and lifeless.

An Old Colonial Chair Used By Washington.

HOUSEHOLD FURNITURE, OLD AND NEW.

Architecture has frequently been called the mother of the arts. The laws which govern the designing of decoration and furniture are closely related to those which govern the building art. The greater art encloses the lesser.

In the work-a-day world we can hardly imagine a successful designer of furniture, without any knowledge of architecture. And those who have this knowledge primarily, before taking up the designing of decoration and furniture have an immense advantage over their fellows in the grasp of general principles and sense of fitness. Let it not be thought that the architect can drop his architectural work one day, and the next day blossom out as a full fledged furniture designer. In every art the technique has to be learnt, an apprenticeship has to be served.

The designing of such pieces as cabinets, bureaus, drawers and bookcases, naturally comes easiest to the architect, whilst the designing of chairs will be more difficult to master. Indeed the designer who can turn-out a chair that is at once the acme of beauty and utility, comes nigh to perfection in the art of furniture designing.

If we were asked to define in one word the measure of the highest art and skill in this branch of applied art, we should unhesitatingly say, "proportion" first, last and always, proportion. The balance of solid to void of curved forms with straight forms, and so on all through the gamut of form, and color also, if varied color is employed on the object.

Twenty years ago, the writer, having served an apprenticeship of twenty years to the art of architecture, entered upon another apprenticeship to the art of furniture designing, in which he still continues. These notes are largely the cumulative result of his experience during that time.

In the year 1883, Richardson the architect of Boston, was in the zenith of his power. The influence of his style pervaded furniture also to some extent. A revival of "colonial" work had also then set in. To-day Richardson's influence is dead, but the "colonial" revival has grown and broadened. The art of England of the eighteenth century is to-day in the ascendency and almost paramount in its influence. This has not come about wholly as a mere fashion, such as affects our dress, but rather as a matter of selection; we have sought those old types because we found they suited our mood and the thought of the day. Moreover we found them comfortable and pleasing to the eye, and last of all they have saved us the trouble of much thinking for ourselves in these hurried times.

It cannot be denied that the desire to possess old furniture as home furnishing or to copy direct from old examples has been inimical to the progress and development of original design.

It must be dampening to the ardor of a designer, brimful of new ideas, to be told by one patron to copy an old chair, the property of another patron. Occasionally this is done without as much as asking the owner's permission, amounting to a barefaced act of piracy.

While the current trend of late years has been more and more to copy from old examples there has recently been evolved a freer style known as L'Art Nouveau. This undoubtedly sprang from the first work of the Arts and Crafts Society in London. The French and Germans caught the prevailing new ideas until now we have travesties of the originals and things produced that might be appropriately called "nightmares" of design, worse in form than the most debased rococco work of the Louis XV period. A reaction from this towards simpler and severed forms will assuredly follow.

With the second half of the eighteenth century a change in the prevailing style of English furniture set in. Sir William Chambers, R.A., an architect, and later Robert Adam, another architect, designed furniture. Many of the latter's designs were carried out by Gillows, a firm of furniture makers still in existence in London under the name of Waring Brothers. Chippendale, Hepplewhite and Sheraton were designers and makers of furniture, whose names have become associated with the work done in England during this interesting period. Robert Adam, who had travelled in Italy, shows in his work the influence of Pompeii and Roman architecture. One of the most beautiful examples of furniture belonging to this period is a dressing table of satinwood with painted decoration, in the South Kensington Museum (see illustration pages). Towards the end of the eighteenth century satinwood from the East Indies came into use in England. It soon became a favorite wood for pieces which were decorated with color.

There were several artists who had come to England from Italy who were employed in decorative painting on panels of walls and ceilings, and who also painted decoratively cabinets, tables and chairs. Sometimes a darker colored wood was used for oval medallions, on which were painted figure subjects classical in character. This contrasted well with the surrounding yellow color of the satinwood.

Pergolesi, Cipriani and Angelica Kauffman were employed by Robert Adam, the architect, in decorative work. The painting on both of the dressing tables illustrated is the work of the last named artist, who was one of the two lady members of the Royal Academy at its inception.

The satinwood chairs of this period are particularly fine, being comparatively simple in form and free from much molding or carving as objects decorated with color should be. The time is known as that of Sheraton and Hepplewhite, although there were many other makers of furniture who worked in the same style. Both of these noted makers published books with designs for furniture.

For drawing rooms, boudoirs and bedrooms where enrichment is desired, this treatment of color decoration on satinwood or mahogany seems particularly appropriate. Other woods besides those named may be used provided they have a beautiful figure or grain; for painted decoration needs this by way of contrast, as a background, which should have enough glossy polish to bring out all the natural beauty of the wood.

In our workshops we have not as yet exhausted the possibilities and variety of colors to be obtained by staining woods, which is a perfectly legitimate method of obtaining artistic effects in furniture.

The proper treatment of such fine grained woods as Mahogany and Satinwood is to leave broad surfaces to display their beauty when polished just as we treat marble, and not to introduce much carving. On the other hand such woods as oak which are of coarser fibre lend themselves to more ornamentation and are suitable mediums for a liberal amount of carving.

Oak should never be left its natural color in the process of finishing. There is no reason why the mellow colors which oak assumes through age should not be imitated, in order that a more pleasing harmony of color may be obtained in the room, and to avoid the rawness of natural color. Some of the best effects are the result of staining only, with little or no shellac, leaving an unpolished surface. The process of staining oak by fumigating with ammonia is much practiced in England, and often fine effects of rich brown colors are obtained by this process.

The wood known as English Brown Oak is sometimes used along with the ordinary Red or White American oak in panels. The variegated figure of the brown oak contrasts well with the native oak which is stained to match it in color.

Prima Vera, generally known as White Mahogany, is sometimes used as a substitute for Satinwood. It has not the same beauty of surface, but it takes a stain well, and can be finished the same color as satinwood.

The woods most in favor at the present time for furniture making are mahogany and oak.

The difference in quality of workmanship and design, between the ordinary work of our day, and that of, say a century and a half ago, is largely due to a lack of special artistic interest in furniture generally and the extensive use of machinery.

The wholesale multiplication of elaborate pieces, nearly all machine made, robs the work of its individuality and takes the very soul out of it.

The whole traditions of the craftsman which were formerly handed down from father to son are lost. The thing produced has no longer any human interest for us. Machinery has its uses but it can never take the place of human thought and human feeling. Not infrequently it happens in these days of rampant commercialism that an excellent design for a piece of furniture is simply killed by altering the artist's working drawing so that the handwork is wholly eliminated. The machine does every part, the result being a machine product which may serve its purpose but never can be wholly satisfying to our artistic sense which craves beauty.

How then are we to obtain the highest and the best results in the making of furniture? I am inclined to think we will have to return to some at least of the good old ways, when the cabinet maker was more of an artist and a craftsman than he is now. We must not let machinery run away with us, and think we can turn out satisfying work by making a gross of pieces at a time. Chippendale and his immediate successors when they set about making chairs, did not consider how they could save seventy five cents on each, by getting a machine to do the work of the carver. If they had followed such a plan their work would not have lived ten years after them. No, it is the human artistic quality after all that gives the lasting value to everything we use. Therefore I say have things specially designed by an artist if you can afford it and made by a craftsman, and pay each a just price for their work.

I have often observed how the young architect when about to marry sets about the furnishing of his house. Most likely during the engaged period or before, he has been picking up at random, odd old pieces in his rambles here and there. Perhaps a four post Colonial bed, a bureau, some mirrors and a few chairs will be in his collection, and it is astonishing how easy it is to furnish rooms with such things.

Whatever else is needed he frequently designs for himself, often of the simplest form (as befits his slender purse) such as a clean carpenter can make. Instinctively he avoids the furniture "slaughter houses." Whatever things modern he may buy, he exercises with good judgment the spirit of selection.

In selecting or designing furniture for his clients the architect will be safe in following out generally a somewhat similar plan, modified and governed of course by the money available for the housefurnishing. The best results are not always attained in those houses where money has been lavishly spent. To design richly, to use costly materials, is often more trying to the architect or designer's skill and judgment, than in work where very limited means are at his disposal.

There is no doubt whatever that, with the rapid growth of Canada, with the Dominion's increase in wealth, a time in the near future will soon come when Art—and that of the very highest kind—will be discriminatiny called into service to beautify the homes throughout the land.

Robert Brown.

ODE TO AN ARCHITECT (?)

(CONTRIBUTED.)

When 'Omer smote 'is bloomin' lyre,
He'd 'eard men sing by land and sea;
An' what he thought 'e might require,
'E went an' took—the same as me!

The market-girls an' fishermen,
The shepherds an' the sailors, too,
They 'eard old songs turn up again,
But kep' it quiet—same as you!

They knew 'e stole; 'e knew they knowed.
They didn't tell, nor make a fuss,
But winked at 'Omer down the road,
An' 'e winked back—the same as us!

—Kipling.

L'ART NOUVEAU.

A new movement in art is worth looking at with respect in the first instance. It is usually a reaction from some artificial state that wants reformation, and the new movement may be regarded as a protest. L'Art Nouveau seems to be a phase of this kind.

As far as can be made out from occasional illustrations, there is one "feeling" running through it all, and this may be roughly described as a feeling for freedom. Always supposing that art is possible at all under conditions of freedom, what is it they want to be free from? The worst examples appear to want to be free from everything, and would probably be brought by its authors under the sentiment of "art for art's sake," which has a noble sound, but about as much sense as "a stick with one end." It makes one's brain crack to try to think of Art existing by itself and for its own sake. It is impossible to conceive of Art except as concerned in the making of something; and Art consists in making it properly. Over what makes proper making the battle may rage, but it has got to be all

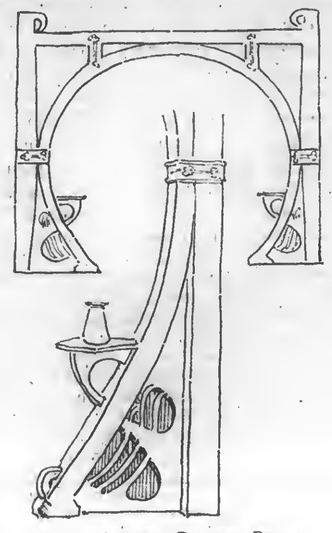

FIG. 1.—ARCHWAY BETWEEN ROOMS.

about making; that is to say an artist's work must represent the purpose for which it was made as exactly as a machinist's; and therefore that part of the new art, that aims first at being unrestrained is not likely to go far towards any purpose the New Art movement is serving in the history of art.

The essential peculiarity seems to be form without reason. The designer in all probability thinks that beauty of form is an abstract quailty. Is there not a "Line of Beauty" over which Hogarth took a lot of trouble? There is; but it does not appear anywhere in a Greek temple. There are evidently circumstances which modify the application of abstract curvature to building. It does not require much reasoning to know that the worst manifestations of the New Art are wrong; the eye is sufficient. A room abandoned to its utmost effort (many such are shown in the German journals) is perhaps the most unquiet thing ever yet produced in the way of architectural finish; the whole room is writhing; it is like nothing so much as being at the bottom of the sea amid the sinuous seaweed. Examined in detail the trouble appears to lie in shaped wood—not square stuff but boards. This is always an unpleasant kind of work; enjoying the distinction of being both heavy and trifling, even when it serves a recognizable construction function; so that it is anything but pleasing to find it done for its own sake, unreasonably. An evidence of the unreasonable character of German Art Nouveau curves is the prevalence of the horse-shoe, the type of the fantastic in architecture; a form which is sure to give a character of superfluousness, even when the opening arched in this way is of brick or stone and the greater part of the form is constructive: when it is shaped out of boards and makes an arched opening between two rooms, as frequently appears in German drawings, the force of Art for Art's sake, can hardly, one would think, go much further. If there is no other reason against it, imagine the danger to which a gentleman would be subjected when,

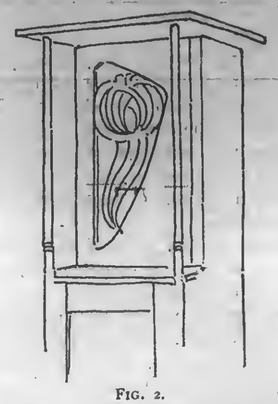

FIG. 2.

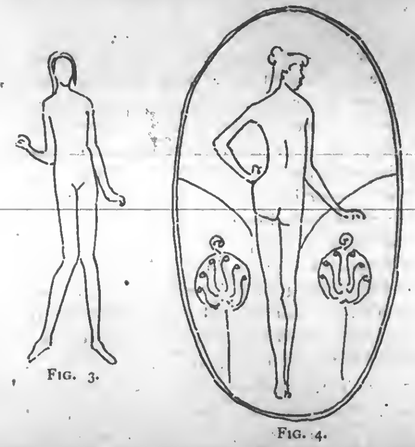

FIG. 3.

FIG. 4.

giddy with the writhings of the trimming, furniture, and wall decoration of one room, he attempted to pass into the next, through an archway which is 6 feet wide at the level of his eye but only 4 feet 6 inches on the floor.

The door of the cabinet in Fig. 2, is a good illustration of the result of letting the wayward fancy roam. This is an extreme case perhaps, but there is nothing like an extreme case to show the way things are tending, and it is rather interesting that the same volume gives a couple of pieces of wall decoration, which seem to show that the influcnce of freedom and the

jig saw are felt in the conception of the female form. This is truly new art. Representations of women are usually said to be either intellectual or sensuous; but here are figures which are neither.

In its more moderate form the shaped board style of work is shown in such forms as the door architraves

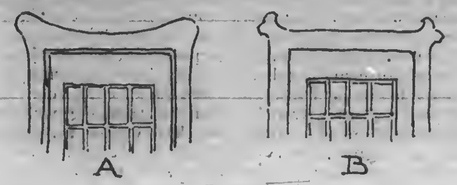

FIG. 5.

in Fig. 5. It is evident that the feebleness of A can only be corrected by the br tality of B.

There is no life in this sort of effort alter shape for shape's sake, and when people to whom fashions in art serve the same purpose as a poster—something to attract attention for a while because it is new—find it has served its purpose, this branch of the New Art will fold its tent like the Arabs and silently steal away.

Of the same order as this amorphous shaping of material are the French statues growing out of a crude block of marble, and their unconfined architectural carving and flowing lines of moulding. It is all apparently at bottom a reaction from the conventions of classical architecture, and the mistake made is in confusing with the conventions of style conventions which are essential to satisfactory expression in all building; in rejecting both the prevailing horizontality of classical architecture and the use of the mouldings by which it is expressed; in avoiding right lines altogether or making them run the other way. Mr. Voysey, whose own work is allied to reactionary ideas, complains in an article of the excess of verticality.

Gothic architecture may be vertical in feeling but there is nothing sits so well upon the ground; its masses take care of that both in plan and structure; in fact, as a school of design which was essentially structural, it could not do otherwise than express, by the facts of its construction, the law of gravity which is the basis of building. The conventions of classic architecture express the same thing in an abstract manner, emphasizing for the greater satisfaction of the eye its repose under a law of which we are always unconsciously conscious. If the New Art wants a change, it must devise a new convention on the same lines, or else a new law.

It is quite otherwise when it comes to movable furniture. Here the freedom of the New Art scores over Michael Angelo; for such furniture is not building but joinery. Its conditions of stability are not vertical pressure. Its tenons are fox wedged or pinned, which give its joints tensional strength; or glued, so that their strength comes from suction, due to the pressure of the atmosphere, which follows the law of fluids, pressing every way. Furniture is made to be both lifted and loaded, and its construction has various tensions to express as well as vertical resistance. The joints are therefore absolutely devoid of expression and to ignore them is the proper policy. The grace of Colonna's furniture, shown in illustrations of the Maison Bing in the Studio and Architectural Record, is mainly due to the vertical and horizontal lines, both of which are severely simple, meeting with a slight curve. This does not at all express the joint, which comes somewhere in the curve; but it is exactly the right expression to the eye of the perfect union of the work at the joints; the union of parts in an article which is intended to be moved. The same thing may be expressed by a projecting tenon and pin; but the "honesty" of this work is not carried far enough; if it proclaims itself movable it ought to be so, but it usually is not. Colonna's furniture is light and its expressiveness is more delicate than in the furniture of our rude (and strong) forefathers. The joints (to return to them) are emphatic points in his design, like the corners of a picture frame, but no more. He usually emphasizes them still further by knots of carving which are not intended to be read, as it were, in one direction but are worked over the joint.

To sum up, because it is time, not because the subject is fully treated:—l'Art Nouveau has probably arisen as a reaction from the over rigidity of system in classical design. But the reaction is everywhere; the New Art is but one phase and for the most part not a very good one. There is as much reaction in Mr. Belcher's Institute of Chartered Accountants as in the greatest vagary in Paris; it is just as much alive as any piece of New Art and likely to remain alive much longer.

W. A. LANGTON.

HEATING AND VENTILATION OF BUILDINGS*

BY R.C. CARPENTER, Professor Experimental Engineering; Cornell University.

In the time which can reasonably be devoted to a consideration of this subject, only a few elements relating to the important art of heating and ventilation can be diseussed. I have selected consequently certain phases of the question which I believe would be of interest to architects and which I thought would lead to a practical and valuable discussion.

TEMPERATURE REQUIRED.

The requirement for heating varies in different countries and under different conditions so that propositions and rules are very rarely of such a general nature that they can be applied without some modification due to surrounding conditions. On the continent of Europe 15° Centigrade, corresponding to about 59° Fah., is considered a comfortable temperature; in America it is the general practice and custom to maintain a temperature of 70° Fah. in dwellings, offices, stores and most workshops, and a heating apparatus is considered inadequate which will not maintain this temperature under all conditions of weather.

EFFECT OF MOISTURE.

The lack of moisture in the air is in a large measure responsible for the demand for such high temperatures in our inhabited rooms. In buildings warmed without an additional supply of moisture, the relative humidity becomes very low and as a consequence the air develops an excessive greediness for moisture and a capacity for drying out all furniture and removing all moisture from bodies with which it comes in contact. Outside air usually contains from ½ to ⅔ the amount of moisture required for saturation and as a consequence it exerts only a slight influence in evaporating fluids from the body or from other materials. This same air if warmed to any considerable amount develops a great capacity for absorbing or evaporating more moisture and as this evaporating process is one which removes heat from the human body, it no doubt accounts for the demand for a hot room provided it contains dry air. This is well illustrated by a consideration of the capacity for holding moisture by air at different temperatures. Thus, one cubic foot of air at a temperature of zero is saturated by .56 of a grain, while air at 70 degrees temperature requires very nearly 8 grains to saturate one cubic foot. This indicates that if air of zero degrees temperature be drawn into a room and warmed, nearly 7½ grains of moisture per cubic foot must be added to maintain it in a saturated condition, or about 3¾ grains would be required to maintain its relative humidity at about 50 per cent. of the saturated condition, or say in a comfortable condition. Since 7000 grains make one pound, this calculation would indicate that more than one pound of water must be added for each 2000 cubic feet of air introduced in order to maintain the room in a comfortable condition so far as the degree of humidity is concerned.

In respect to the supply of moisture to our warmed rooms, all our heating systems are deficient and until

*From Heating and Ventilation, N. Y. John Wiley & Son. (4th Edition)
†Paper read at the annual convention of the O.A.A., Jan., 1904.

very recently little attention has been given to the matter. As a result, most of us are accustomed to live in houses which have an atmosphere dryer than the air of the dryest desert, which air tends constantly to draw, by a process of evaporation, moisture from the bodies of the inmates which on the other hand produces a feeling of chilliness and discomfort that can only be overcome by an extremely high temperature. I believe that this fact accounts for the habits already pointed out, viz, that we require higher temperature in order to be comfortable than the inhabitants of Europe. I believe in this respect, too, the residents of Canada will be found to live in even a dryer atmosphere than that common in the States and as a result they require a higher temperature in order to be comfortable. These considerations point out the importance of supplying the proper amount of moisture to our heated rooms. There is little doubt but that a proper degree of humidity would result in a decided saving of fuel and would probably improve our sanitary conditions.

NEED OF VENTILATION.

Systems of warming with and without ventilation exist in large numbers; those without ventilation being greatly in excess of those with. A system of ventilation is frequently regarded as a luxury which is only applied where sanitary conditions are such as to make it absolutely necessary, but systems of heating are so essential to a comfortable existence and even to life itself that they must be installed in practically all inhabited buildings in these latitudes. Systems of ventilation are not so vitally essential to the human existence especially if the health be disregarded, for it is a fact that people who are unaccustomed to pure air may be very comfortable in air which is charged with organic organisms and various deleterious gases; the effects, however, of breathing impure air, while not producing sensible uncomfortable sensations, are much more serious than living in cold rooms. It will doubtless require argument and persuasion to induce people to install a proper ventilating apparatus, since such apparatus adds both to the first cost of the construction and the operating expense. It costs money to warm buildings; it will cost additional money to properly warm the air which is needed for thorough ventilation. Considerations of comfort require the building to be warm, sanitary considerations require the building to be ventilated. If people could be made to feel that the cost of ventilation was a better investment than the cost of a physician, there would be no lack of pure air no more than there is of a high temperature in our present buildings.

The greater part of our buildings are heated by some system of direct heating especially when steam or hot water are employed as the heating medium, and in such cases the only ventilation which we find is that accidental ventilation due to the entrance of air around door and window frames or that which enters when doors may be opened as people pass to and from the room. In dwellings where only a few people live, systems of heating may exist with good sanitary conditions, but where a large number of people use the same room, additional air must be supplied, otherwise the sanitary conditions will be bad and the effect on the health of the inmates will be serious.

HEATING IN CONNECTION WITH VENTILATION.

While large supplies of air may be drawn in to a room by a heated chimney, such a system of heating air is not economical nor is it at the present time very extensively used. When air is required for ventilation it is at the present time generally supplied by a pressure blower which is so arranged as to force the air over a heating surface on its journey to the room so that it will enter the room without causing the inmates any sensation of chilliness. The systems of heating in which the blower is employed for delivering air into the room vary in character; in some of these systems the entire heat required for the rooms is brought in by the the entering air which is forced over a heating surface and warmed sufficiently to accomplish this result; in other systems direct radiation is placed in the rooms to be warmed and the entering air is heated only to a point necessary to remove its chilliness which is usually a few degrees above that of the required temperature of the room. In some instances the entire heating surface for a building is massed in one place and the air is forced from this location to all the rooms; in such cases means are usually provided for by-passing the air around the heater in case the temperature becomes too high, arrangements being introduced for supplying a constant volume for ventilation purposes regardless of the demand for heat; in other cases the heating surface is subdivided in small parts and the air for each room is warmed separately from that for the remaining portion of the building. In carrying out these various systems, heating engineers have shown great versatility and great adaptability; in a few cases they have been prevented from producing the best results because of lack of space in the building and because the architect did not have an intelligent idea of the work necessary. It is perhaps unnecessary to mention that ventilating apparatus requires room in order to meet all the requirements of modern sanitary science and this room should be located with judgment and so as to permit of the proper erection of what are essential features of modern sanitary construction.

RELATIVE ADVANTAGES OF HOT WATER AND STEAM HEATING SYSTEMS.

In systems of heating by hot water circulation, the heated water rises and the cooler water falls by reason of difference in weight; in many respects a system of hot water circulation is an ideal one; this is especially true with reference to temperature regulation for if the radiators are properly proportioned the temperature of the radiator may be modified or regulated by the supply valve so as to maintain any desired temperature in a room. This advantage is also an economical one when the weather is moderate and as a result it is generally found that hot water heating systems require less coal than steam for an entire season's heating.

Steam heating surfaces can be made much smaller than hot water surfaces for the reason that the temperature of steam can be made considerably in excess of that which is practically possible with hot water radiators. They are open, however, to the objection that the temperature of the radiator cannot be changed by varying the opening of the supply valve, so that in order to regulate the temperature in a steam radiator the steam must be alternately all turned on or all turned off. It is, of course, possible by manipulation of the air valve to render some of the heating surface in a radiator inoperative, and this makes possible a method of regulation which, while effective, is exceedingly troublesome for the reason that it is dependent upon constant manipulation of steam and air valves. Practically, however, the temperature of radiation in an ordinary system of steam heating can only be regulated by turning all the steam on or all the steam off.

Steam heating systems are less costly than hot water heating systems since the radiators are only about five-eighths as large, and the radiators of such systems are less conspicuous and generally more desirable.

VACUUM STEAM HEATING SYSTEMS.

During the last few years many improvements have been made in steam heating systems with the intention of overcoming the defects and of making the system of steam heating in every respect as desirable as that of hot water with the additional advantage of using smaller and less conspicuous radiators. It is a well-known fact that, as the atmospheric pressure is diminished, water will boil at a lower temperature, or, in other words, steam formed under such conditions would have a lower temperature than that formed under atmospheric pressure or one higher than atmospheric. It follows from this, then, that if the pressure in the apparatus used in steam heating can be varied to suit the requirements for a higher or a lower temperature, we can obtain in a steam heating system all the advantages pertaining to the present steam heating apparatus for cold weather and all

those which pertain to the hot water heating apparatus for mild weather. Such a system in order to be successful would be operated when the weather was cold at atmospheric pressure or slightly above, in which case the temperature of the steam might vary from 212 deg. to 220 deg. Fah. With a milder temperature pressures lower than atmospheric could be had provided the atmospheric pressure were nearly removed from the system, in which case we might have a boiling temperature and steam corresponding to the pressure which would vary from 150 deg. upward. In the Paul, in the Webster, and in the Johnson system the vacuum is produced by an independent air pump which removes mechanically all the air from the system. In the Morgan system and several similar ones the air is removed through a mercury trap by applying pressure for a short time to the entire system, arrangements being used which prevent the air from entering after it has once been driven out.

The first three systems referred to are evidently positive in their methods of operation and have proved to be eminently practicable and satisfactory in the heating of large buildings where power is available for removing the air. The Paul and also the Webster system is eminently suited for the use of exhaust steam since each provides practical means of circulating exhaust steam without the addition of back pressure on the engine. The use of exhaust steam for heating very frequently permits the saving of large quantities of coal, for the reason that exhaust steam which would otherwise be wasted may frequently be made to answer every requirement for heating, without the necessity of burning additional coal.

Large buildings which are constructed for office, dwelling or factory use usually contain steam plant for elevators or other power purposes. The exhaust steam from such a plant may frequently be sufficient for warming the building during the cold months and should if possible be utilized for that purpose. The Paul or the Webster systems can be installed without the expense of pipes of extra large size and in this way present an opportunity for great improvement in economy of fuel and in obtaining satisfactory results at much less cost than the older processes.

The vacuum systems without the use of power devices for removing the entrained air require excellent workmanship, but if properly installed are very satisfactory and will produce excellent results.

IMPROVED HOT WATER SYSTEMS.

Some attempts have been made to improve the heat carrying capacity of hot water by adding some substance which would decidedly raise the temperature of the boiling point. While such substances are known, the cost at the present time is too much to preclude any extensive commercial use. If we could raise the temperature of the boiling point of hot water without increasing the pressure, smaller radiators could be used and the objections to that system which now exist would be entirely removed.

Among the chemicals which are found well fitted for use in a hot water heating system, the chloride of calcium is perhaps the most prominent. Its expense would, however, prevent its extensive use. Common salt (chloride of sodium) is entirely unfitted for such a purpose for the reason that it rusts any iron material with which it comes in contact.

Hot water has also proved to be an admirable medium for use in connection with exhaust steam heating; for such uses the hot water is circulated by a pump and is warmed by passing through a metallic heater so arranged that the exhaust steam comes in contact with the outer surface of a series of tubes and the water to be heated comes in contact with the inner surface. This system has been applied by Evans & Almirall of New York to the heating of large establishments and small towns and has proved admirably adapted for such purposes.

High temperature can be obtained in hot water heating systems by omitting any expansion tank and closing off any connection with the external air; such a system being known as a high pressure system. Such systems have been frequently installed but they are exceedingly dangerous, for the reason that the pressure increases as the temperature is raised, with the result that unless appliances for protecting the apparatus be installed and maintained in perfect order, a pressure sufficient to cause an explosion is likely to be produced. I cannot too strongly argue against the use of a pressure system of hot water heating for the reason that I think it is too dangerous to be seriously considered as a possible means of heating. Happily, I believe that this system has been pretty nearly abandoned both in Canada and in the United States, although I have recently heard that a system of hot water heating has been employed in Canada in which valves were used in the return pipes and located in such a manner that they could be closed during the operation of the heating system and in fact were so closed, the effect being to produce an over pressure and a serious explosion. This calls attention to the need in all hot water heating plants of constructing a circulating system so that it cannot possibly be obstructed either by accident or otherwise.

HEATING WITH HOT AIR.

Heating by hot air circulation or from a furnace which is located so that the air entering the building will pass over a heated surface and thence flow to the various rooms to be warmed, is well adapted for small buildings and gives in many cases excellent satisfaction. A system of furnace heating is not well adapted for carrying air long distances horizontally for the reason that the motive force which induces circulation is extremely small and liable to be overcome by adverse winds. Systems of furnace heating are frequently illy designed and poorly erected and as a result this method of heating has gone into considerable disrepute. In many cases extremely small furnaces have been used and in order to obtain sufficient heat, the heating surfaces have been kept extremely hot, thus overheating a limited amount of small air; this comes from an attempt to make small volume of air heated to an extremely high temperature do the work which should be done by a large volume heated to a moderately low temperature. A hot air furnace with ample heating surface in proportion to grate and installed with well proportioned hot air flues and with exhaust flues leading from each room into the attic can be made an extremely satisfactory and desirable method of warming a 10 or 12-roomed house. The furnace should be installed as closely as possible to the windward side of the house so as to utilize as far as possible the natural air circulation to aid in the distribution of heat; it will generally be found much more satisfactory to co-operate with natural forces than to oppose them.

CONCLUSION.

In conclusion I would say that I have in this short address intended to call attention only to desirable and undesirable features in several of the most prominent systems of heating and ventilation. I have carefully avoided the discussion of detailed methods of design and the methods of proportioning the various parts of a heating and ventilating system for the reason that such methods are fully and exhaustively treated in well known text books on the subject and moreover could hardly be considered in the limited time at our command. I have myself endeavored to discuss the various questions of such design in a book on the subject of Heating and Ventilation, which I believe is accessible to all the members of your Association.

I am much pleased at the interest taken in this important branch of building construction by the members of your Association as I am thoroughly convinced that comfortable and healthy buildings are of equal importance with noble and artistic ones. There is no reason, however, why buildings should not possess all of these attributes and I am pleased to learn that the members of your Society have done so much towards solving the questions relating to the construction of both sanitary and beautiful structures. The architects of Ontario already occupy an honored position in the reputation of the world because of the artistic, noble and useful structures which they have produced; let us

hope they will not neglect to provide for all the elements which tend to comfort and healthy living, and that they will in the future as in the past continue to apply the most perfect systems in heating and ventilation.

DISCUSSION.

The President: Gentlemen, as I said before, we wish a full discussion on this paper of Prof. Carpenter's. We have with us this afternoon men who are quite capable of discussing and asking questions that may be pertinent to its subject; it is perhaps the most important subject we, as architects, have to deal with, for after all it matters not how beautifully we design a man's dining room or how artistically it is decorated and furnished, if he comes down in the morning and cannot get the room up above 60 degrees. Therefore I think Prof. Carpenter's paper is upon a subject we cannot pass lightly. As we have him with us it is possible he will forgive us for asking him a few questions on the subject.

Mr. S. G. Curry: Mr. President and Gentlemen, I have much pleasure in moving a vote of thanks to Prof. Carpenter for the very instructive paper he was kind enough to read to us. I do not know whether there is much room for discussion, because I agree with nearly everything he said. I think where there is a disagreement there is usually more discussion than where there is an agreement. There is only one point raised that I should be inclined to question, and that may be theoretically correct. It is with regard to the variation of hot water and steam surface. I find it is necessary to have 2 to 2½ times as much surface for steam in our climate; it may be due to the fact that I am in the habit of not using more than a pound pressure. In lieu of the gravity system a system arranged for working practically with little or no pressure, we have a system with little or no force in it running up four or five pounds of steam. Under these conditions possibly the proportions Prof. Carpenter states are practically correct, more theoretically correct than in fact, because like all these things it is a question how you consider the matter. I have been in the habit of figuring steam by the pound or less; and as far as I know I find my arrangement has answered every purpose satisfactorily. The address has been most satisfactory; in fact it has taken up all the different points in a thoroughly practical and sensible manner. It has gone over the history of heating pretty thoroughly and it is put in a very plain and comprehensive light. I do not know as I am in a position to do any criticising. As I said before, I agree with nearly everything that has been said, and I wish to compliment the Professor on his paper being most thorough in every point, and satisfactory; and I am quite satisfied it will be of great benefit to the members of the Association.

Mr. Burke: I have very much pleasure in seconding Mr. Curry's motion. I must express my surprise at the improvement in heating that is displayed in the "vacuum" system; the small water power is certainly astonishing compared with the amount of power required where they are depending on pressure to force the heat through the pipes. I have a system today in use where it is almost ridiculous to see the amount of water power that is used for the large quantity of surface to be heated; and yet the building is being heated. In regard to the exhausts I did not understand whether those were exhausts which where taken back to the furnace or taken back to the outside. I had a little experience in my own house with regard to the exhausts; I could not imagine why one of the flues would not heat and I went to the one built connected with the chimney and I found a great amount of cold air coming into the flue and passing from that down to the furnace, making it impossible to heat the room.

The President: I see we have several well known representatives of the trade here, and some of them may have had practical experience in those systems. Can we not hear from one of them?

Mr. Purdy: Mr. Gurney, Mr. Mansell or Mr. Armstrong.

Mr. Armstrong: I have had no practical experience in the use of any vacuum system, but I am interested in the description of the Morgan system, and I would like to ask what is the height of the column of mercury that they employ. I also notice he takes the air pipes and returns them to the boilers. I am very much interested in that, and if Professor Carpenter will give us that information I am sure every member would be delighted to hear him. Another point, the proportion of 1 to ⅔, I would like to ask if that is hot water at 212 degrees and steam at 212?

Professor Carpenter: In regard to the question asked by Mr. Armstrong, first, in respect to the apportioning of the radiating surface of hot water and steam, it is rather interesting in the way it came out. I figured it out on a theoretical basis that the proportion ought to be about 100 to 164; and the American Society of Boiler Makers, from an entirely different system of figuring, concluded that 166 would be the equivalent of 100 of steam. I got at it in an entirely different way from that but the results were the same I think from a theoretical and practical standpoint. We are now putting in radiators in that proportion, that is, giving the one and two-thirds square foot of hot water radiators where we put in one of steam. The whole thing depends on the temperature you run your hot water radiator at. This calculation is based on hot water about 180, as you will find if you calculate it through. If you run them at a lower temperature the radiators would have to be larger. That has got to be an almost standard practice; it was adopted almost unanimously after a long discussion by the American Boiler Makers; I was present and took part in the discussion at the meeting at which they adopted it. Regarding exhaust flues in the hot air furnace. I had in mind what I have often done in the hot air systems, that is, carrying exhaust flues up into the attic, not putting them outside because that leaves them in a position by which we can draw the cold air down into the room. But I have found in nearly every case that if these flues are simply carried to the attic they are certain to keep the system in equilibrium without bringing in cold air; but the hot air system is subject to vagaries; one sometimes finds the hot air going out through the cold air box, and the cold air coming out through the warm air flues.

Mr. Armstrong: I would like to know if the temperature the steam gets to at 120 is equal to the steam raised to 212 degrees in the vacuum? I understood that, you raise some hot water at a temperature of 120 degrees in the vacuum system. I would like to know if the steam is the same temperature as that raised from hot water at 212 degrees.

Prof. Carpenter: That depends. Steam is at an absolute pressure of two pounds per square inch. The atmosphere gives us fifteen pounds per square inch; if you pump up thirteen pounds that water will boil at 126 degrees; the steam would be abont that temperature 120 degrees; with the whole atmospheric pressure of 14 2/16 pounds steam is formed at 212 degrees. Steam at two pounds pressure would be formed at a temperature of 216 degrees. So that you see if we can reduce the pressure we can get almost any temperature we desire with the steam. And that was the intention with these systems.

Mr. Gurney: Do you consider the system of hot water heating, where the water is super-heated under pressure, getting the water so much hotter, an economical way of heating it?

Prof. Carpenter: The pressure system of hot water heating was given up because it was believed to be dangerous. I have never felt that it was safe; there are so many things which might happen, especially when you consider how the water is managed in the ordinary domestic heating. It seems to me it is almost suicidal on the part of people to use it; and for that reason I have never felt safe to recommend it. I would recommend it if we could raise the boil ng point of water without increasing the pressure, by putting in glycerine or something of that kind: but the objection to that is the expense.

Mr. Gurney: In using glycerine is the circulation as perfect as without it?

Prof. Carpenter: Yes, it is perfect. We have been conducting experiments with glycerine, and it does very nicely.

Mr. Gurney: May I ask what percentage if calcium chloride would be required?

Prof. Carpenter: I could not tell you that exactly, but it is a two-thirds diluted solution. Practically that won't do because it acts very actively upon the iron, rusts it. The chloride calcium does very well, but we found it damaged brass very slightly. Glycerine is the best; it don't attack any of the metals and gives practically excellent results; but it costs too much money.

Mr. Mansell: Is it possible to make any attachment to a hot water system to put more humidity in the atmosphere or in the air of the room. We understand that a certain amount of moisture produced the requirements, in the temperature, in the atmosphere. Is it possible to make any artificial attachment to a hot water system to give us a proper degree of humidity in the air

Prof. Carpenter: Perhaps I am not well prepared to answer that question, but I do know that an article of that kind has been put on the market by the Johnson Electric Company people, who furnished the automatic controlling device for regulating temperature, and it is claimed by them to operate very successfully. But I have had practically no experience with it. It consists of a device which is operated by a cat-gut which is very susceptible to a change in the humidity of the room; it will shrink very quickly with the dry air, and stretch with wet and let out steam or water until the cat-gut goes back to its proper form. That is the principle of the device, and it is claimed to work very perfectly, but I am not prepared to say how much of a success it is practically.

Mr. Gurney: There has been a radiator invented by one of the Ontario Society of Architects in which the top portion holds water, and it is evaporated by a heating device inside but it is not controlled in any way that I know of.

Mr. Mansell: How do you fix the radiating surface?

Prof. Carpenter: The method of calculating the radiating surface there is a formula that has been worked up from some experiments which I think is in this form. (Writes on blackboard)

$$\frac{70}{280} \qquad \left(B \times \tfrac{1}{4} W \times \frac{NC}{50}\right)$$

$$114$$

$$100 = 1$$

$$166 = 1\tfrac{2}{3}$$

$$\frac{25}{40}$$

The radiating surface depends on three things, the amount of glass exposure and wall exposure and the amount of cubic feet of air which is heated. This formula has proved to be very serviceable and practicable. The coefficient which we have put down at ¼ is subject to change in different climates. In that formula the coefficient of ¼ gives very satisfactory results in perhaps New York; it is not enough for Massachusetts; it should be about 15 per cent. more, and it should perhaps be about 10 per cent. more for Detroit. I presume for this place it should be something like 20 per cent. more. The formula is worked up on the principle that the difference in the degree of temperature between the inside and the outside air is 70; I think here it might run to 80. The difference between 70 and 80 would in this particular case make a difference of about 10 per cent. The reason it makes a difference of 10 per cent. is, in mathematics, you have 70 divided by 250, and it would be changed to 80 divided by 250; so that something like 10 to 15 per cent. more would probably be required here than with us because our extreme we usually consider zero; but we have colder sometimes than that; last week it was 17 below zero.

Mr. Armstrong: Taken from steam at 230 degrees and a factor of ¼ would it make any material difference whether it was in New York or Toronto if you took an outside temperature at zero and 70 degrees inside?

Prof. Carpenter: No. If you run your steam up two or three pounds that would compensate for the whole difference and then you could get along with that formula; I don't see why in extremely cold weather people would not be willing to carry a little more steam provided they did not run it up more than three, four or five pounds.

Mr. Denison: They do not like it above one pound.

Mr. Armstrong: It is not a formula for the first floor alone. Would you change it for the second floor?

Prof. Carpenter: Yes, in this formula I have here it was for the different floors and the hall; for instance for the hall and the first floor we have always taken "N" as three; on the first floor rooms and other than the hall "N" as two; and on the upper story rooms "N" as one; the rule being the N represents the number of changes which would take place every hour, which is premising, but it appears to act pretty closely with residence practice. I like to have a hall very well warmed and this formula throws in each hall a good amount of radiating surface.

Mr. Helliwell: What are the quantities for N and C in the formula?

Prof. Carpenter: C is the cubic contents of the room. N is supposed to be the number of changes of air which occur in the room in an hour. It would be scientifically correct if N were positively known.

Mr. Helliwell: There is one other point I would like to get some information on and that is the efficiency of running cold water through coils with the idea of cooling the air in the summer time with the use of the fan system.

Prof. Carpenter: The converse question of heating is one which has cost a good many people a good deal of trouble. It is perfectly feasible to cool air by passing it over a cold surface in the summer time. For instance, passing cold water through a coil of pipe and then blowing the air over it. That has been tried and been done and is being done in a number of New York theatres during the hot season. The first time the practice was undertaken I think quite a serious mistake was made, that of cooling the room too much. It has been found that it is not safe to lower the temperature lower than the air outside only a few degrees, possibly not more than five or six degrees, because it the air be cooled too much people who go in get chilled in a short time and the effect on the system is dangerous. It is easy to cool the air but it is not safe, for people going into a cool room from the outside are liable to be chilled, consequently this system has not found the favor that was expected, that is, it is not safe to cool the room but very little. If you have 100 degrees outside they have to keep a pretty high temperature inside. If you went went from 100 degrees to 90 degrees inside it might in a little while become chilly. The results have not been as satisfactory as they were expected.

Mr. Burke: Is the humidity in the building an object to a great extent in the fan system?

Prof. Carpenter: In most of the systems where the system is in charge of a janitor—some of the large systems—they require a janitor to take the humidity by means of a wet and dry bulb thermometer, but in a good many of them they don't; although in the last few years there has been a decided tendency to look to the moisture. The whole thing is the supply of the moisture; it has been brought out more possibly during the last few years than before.

Mr. Burke: Has not it been done automatically?

Prof. Carpenter: Only to a limited extent.

Moved by Mr. Curry, seconded by Mr. Burke, that the thanks of this Association be tendered to Professor Carpenter for his very interesting paper and his kindness in answering the questions asked him in reference thereto. Carried.

The President: I do not know whether you customarily find such an inquisitive audience but certainly the questions and answers have been of the greatest service to us.

Prof. Carpenter: It gives me the greatest pleasure

to give any information which I happen to have which you do not. I am also getting a great deal of information from you and thank you very much for your expression in your vote of thanks.

About the system I would put in I would say that I have never been tied down to any particular system. I have frequently installed hot water systems and then steam systems and there would be perhaps no very good reason except I find people prefer one or the other and usually they wanted a system particularly bad. In that case I have had no special reason to recommmend one or the other. I was thinking this afternoon of what I considered the advantages and disadvantages of each system; as to its advantages and then as to its disadvantages I see no reason why we should not be prepared to supply anything that is required especially if we give the people such information as we have on the subject. I have favored steam heating perhaps more than hot water simply for the reason that our steam fitters are not very good workmen ; they are getting much better however and during the last few years the objections we used to find in our hot water jobs have pretty nearly disappeared. About eight or ten years ago it was almost impossible to get a hot water job that worked perfectly. The pipes would not be well put up, not aligned nicely. The pipes would not be rimed ; but that was due to the carelessness of the workmen. But now we are getting better work and we can put in every kind of system. In large buildings, where it is possible, I believe in the vacuum such as the Paul & Webster people put on. I think it pays to put them on because it adds nothing to the first cost. Your circulating pipes can be kept smaller to pay any extra cost due to putting in their system, so that the owner will have no extra charge and he will have a system that is satisfactory. In small buildings or residences I prefer the Morgan system, although I am not prepared to say I would recommend that very universally ; it might not prove to be very good. But from what I have lately seen in it I think ti is a very excellent system. I stand without any prejudice in the matter.

Mr. Gurney : Which do you consider the more satisfactory, the one or two pipe system in regard to operation and economyr ?

Prof. Carpente : That seems to be a question of locality. The steam fitters in New York build a two pipe system ; they do not know the one pipe system ; they do not believe it will work. On the other hand the steam fitters of Chicago don't know anythiug about the two pipe system ; and there is the same prejudice against it; they do not think it will work; as you come out of New York State and Boston you won't find anything but the one pipe system used. It must be a matter of education with the steam fitters. The New York steam fitters tell me it is practically impossible to put up a one pipe system ; they will not put it up, their men will beat them ; and as a rule they do not try to put it up. So far as economy and efficiency is concerned I do not think there is any difference one is as good as the other, both work perfectly ; the one pipe system it seems to me is the only one that ought to exist because there is no use having two pipes when one will to the business.

THE O. A. A. EXHIBITION.

The president and office bearers of the O.A.A. are to be heartily congratulated on the interesting exhibition of architectural drawings and photographs which they were able to get together for the annual convention. The exhibits fall under three heads : Domestic Work, City Buildings, and Decoration. It was a rather noticeable point about the exhibition that there was practically no churchwork. By far the best and most interesting exhibits were of a domestic character—for the most part simple work in brick and stone and shingle. There was a general tendency in cottage buildings to use too many materials and textures for the size of the job to carry, and in some cases a rather strained delight in clapping on colonial adjuncts ; but, laying carping criticism aside, what one can appreciate in the Toronto domestic work is the sincere attempt to solve the problem of building not wholly uninteresting houses which shall in their main characteristics evince as good an English pedigree as that of the people who build them. It is a little surprising not to find the sterner traditions of Scottish domestic work more in evidence—a touch of the severity and restraint which reigned north of the Tweed till a century ago would do no harm in such a suburb as Rosedale. Where so much that was really charming was exhibited it is almost invidious to mention names. The mullioned-windowed house at Rosedale for Mr. Baillie by Messrs. Spoatt & Rolf cannot be passed by, however ; it is a beautiful and scholarly piece of work of very English character. Mr. Gouinlock's design for a straggling cottage country club at Lambton, while striking a more purely Canadian note, is equally charming. We trust that the virulent green shingles of which we see too much was not here proposed to be used. The drawing did not make this point very clear. Messrs. Chadwick & Beckett show a more distinctly American influence in their exhibits which are none the less charming on that account. Both Mr. Gemmel and Mr. Baker evince a predilictiou for English work in two very pleasing drawings at the platform end of the long room, while the photographs contributed by Messrs. Burke & Horwood, Messrs. Symons & Rae and Messrs. Gordon & Helliwell, show us much careful and thoughtful work, thoroughly modern, yet happily not tainted by the virulence of the "Art Nouveau' movement.

Among the city buildings there are quite a number of examples of that modern deformity, the building with its foundation at the first floor level. When will the self respect of architects and the taste of tradesmen combine to stop the silly practice of hoisting five hundred tons of piers and cornices on the edge of a plate glass window 100 feet wide ? When two tiny piers are left at each end of the site this anomaly of design to which steel construction has lent itself is only made the more apparent.

In the series of elevations in competition for the Metropolitan Bank at Montreal we have an interesting contribution to the narrow street front problem. It is the treatment of the lowest story that has given most trouble. Messrs. Darling & Pearson have certainly struck on the happiest arrangement. We have large city buildings illustrated by beautiful wash drawings from this firm, and also from Messrs. Sproatt & Rolph. Both evince a thoroughly sound type of Franco-American architecture, such as is usually found in the better class of sky-scraper ; both evince the drawbacks inherent in this type of building. A comparison is made none the easier by the fact that the illustrations are from the same hand and about as good as wash drawings can be. When architects begin to exhibit their working drawings instead of special productions criticism will become easier and our art will not be a sufferer.

In the decorative work of Mr. Challener there is much lyrical genius for colour and a true feeling for drawing. Decoration, however, is an epic art and requires a bigger, broader kind of design and a simpler, grander scale of colour than is known to that school which finds its highest sphere in the decoration of the ceilings of Paris cafes. Mr. Challener is yet young and the work of the great men is still with us to study. In these two facts there may possibly lirk a great deal that concerns the future of native Canadian decorative art.

Mr. Reid shows some less ambitious decorative schemes and in a tenderer key, but, nevertheless, broad in conception and execution. There is some dainty illuminated work by Mr. A. H. Howard—in this field colour cannot sing too clearly ; to the illuminator it is allowed to rival the peacock's necks with blues and greens ; the poppy's red, the rainbow's graded hues ; the irridescence of the pearl and beads of burnished gold are his to play with.

PERCY E. NOBBS.

THE COLORED INTERIOR DECORATION OF ARCHITECTURE.*

When so large a subject has to be dealt with in so short a time, it is necessary to select some one section or principle to which particular attention may be called, and in looking round to make such selection I find one upon which I have often laid stress before, and which cannot be too often insisted on with regard to decoration. I mean its subservient relation to architecture; its duty of respect to the architecture it is to adorn.

Let us for a time put aside the average dwelling room with no features that can be classed as architecture. Color can do much for it—can give it character, can give it proportion, and can make it lovely or unlovely ; but the result after all is a matter which concerns only the owner and the decorator. They can try what experiments they are inclined to, or what fads they fancy, and they do no man wrong. If the result pleases their friends, they have their reward, and if it does not, they will be satisfied that this is due to want of culture in their friends.

But it is quite another matter if the building under treatment has other than domestic functions, or has received from its author some definite architectural expression ; that is to say, bears some stamp of another man's thought.

When this is the case, it becomes the decorator's business to study that evidence of thought, and to endeavor to enhance its value. In pursuit of this intention, he has first to try to ascertain what lines or what features are really of the first importance in expressing structure and proportion. If he can find these, he must never lose sight of them, for these are the features or lines with which nothing else must interfere.

However varied or however rich the decorative detail of the wholemay be, the final result of colored decoration of architecture should be lucidity of expression. And this is only to be obtained by allowing the due proportion of expression to each feature which has a place in the ideal scheme of structure.

If such expression is really in due proportion, repose —that great element of beauty in all art, but most of all in architecture—is produced. For what is it that produces "repose" in art? It is the immediate satisfying of the mind's instinctive search for something ; and in architecture that something is stability. Now, this stability which the eye and mind demand is not one of which scientific or practical evidence need be forthcoming. It is that of which an instantaneous conviction is borne to the mind by the continuity of suggested lines of strength in reasonable proportion to each other. And it is these lines of suggested strength which color may do so much to explain or confuse. Nor is the explanation altogether so simple a matter. It is as harmful to over-accentuate any of them as to confuse them. The expression of each part must be relative. To exceed the due proportion of expression in any part is to disturb the balance. Blatant expression in color is like shouting one's own language in the ear of a foreigner ; it does not make things clear, and probably gives offence.

Another point which it is desirable to mention, because it is the subject of frequent misconception, is that lucidity of expression does not depend on the use or the use or omission of detail. The most elaborate and delicate detail is compatible with perfect lucidity.

The one necessary thing in using ornamental detail is to take care that it does not interfere with the main science. Used with proper skill and knowledge, it should be able to assist materially in its development. On the one hand, it should assist to explain surface or to accentuate line; on the other it is invaluable as a means of lowering tone and softening effect, without sacrificing purity of the individual colors. Further, it facilitates harmony by giving the opportunity of small "recalls" of colour—of importing, as it were, fragments of one colour into the field of another—one of the most essential conditions of complete success in harmony. This should be carefully noticed by students in examining the pictures of the best masters.

I have said just now that it is the first function of color, when used in architecture to assist in producing that "repose" which results from an instantaneous impression of stability. This means that the eye must be encouraged to recognize at a glance such features and proportions as indicate or suggest well balanced structures, whether that be expressed in the architecture or not; for it must and in fact does, often happen that structure is not outwardly expressed—at any rate not to the extent that allows instantaneous conviction of its sufficiency. A flat ceiling is one example. In such cases color steps in and suggests constructive lines of some sort, which, though they have possibly no relation to the actual invisible structure, suffice to satisfy the eye in a moment as to the balance and stability of the surface on which it must otherwise have hesitated in doubt. Moreover lines of some kind are indispensable to assist the eye and mind to travel over the surface of the building; and whether by moulding or by color, it is the disposition of these lines upon which depends the impression of "repose." If simple and suggesting the relation of one part to another, the eye grasps the meaning quickly and is at rest. But if the lines expressed (whether by mouldings or colors) are inconsequent, purposeless and without proportion, the eye becomes puzzled, restless and dissatisfied. The eye demands a clear path, not a broken wilderness.

To touch on another branch of decoration, and a most important one, the use of pictorial art, in connection with architecture. We are accustomed to hear the most transcendental talk over the idealism or symbolism of the subjects to be painted in this or that building. I am far from under-rating the value of this quality of art. What I want to point out is that it is the building as a whole, if it be a worthy building, which first has to be considered ; and that is the form, the tone, and the treatment or style that affect the building, not the "subject". For the harmony of the building it would not matter a jot whether the subject were "Cupid and Psyche" or "Moses in the Bulrushes." But it may ruin the whole effect, if the picture is in a badly proportioned panel, painted in too cold a key or executed in a style too crude or too complicated for its surroundings. Not one in fifty of even very able English painters has been trained to look at art from this side—or to consider the necessity of keeping the whole tone of his own work in relation to the decorative result in the whole building. Look at the paintings in the Royal Exchange. Not one, or perhaps but one, is in tone with its surroundings; not any two in tone with each

*A paper read before the Architectural Association in London.

other. I regret this the more because I first suggested in a report to the Gresham Committee, dated Oct. 9, 1890, that these panels should be painted historically.

Undoubtedly painting in the studio instead of on the wall itself tends to enlarge the risk of want of harmony with the whole surroundings, though it certainly presents some advantages. To take one disadvantage alone, the difference of light. This is almost certain to be different in degree and quality, and more than likely to differ in direction. This being the case, there is only too much probability of a general difference of tone between the picture and its surroundings when finally brought together. Even the design or cartoon of the picture—color apart—will often need some change, when tried on the spot, from what seemed satisfactory when viewed in the studio.

The colored bands or margins which in colored decoration are so valuable, are more than ever useful when pictorial treatment is adopted in the panels. They afford the means of connecting the more forcible coloring of the picture panels with the rest of the work, and so preventing them from appearing as detached patches. Apart from this function, they greatly facilitate and direct the passage of the spectator's eye over the whole work and aid that prompt grasp of form and surface which I have already spoken of as inducing the sense of repose.

The matters which I have mentioned are practically "axioms" which are absolutely independent of style or fashion. The building may be ecclesiastical or secular, classic or gothic, simple or elaborate, it matters not.

The general principles which should guide decoration are true for all. And it is this main point which it seems useful now to insist upon, because we find so many persons ready to substitute particular arrangements of color or pattern for any real knowledge of art or principles.

Be sure of this, that just as sound principles are independent of style or fashion, of any special harmonies of color, or of any character of design, so no design, no arrangement of color, no excellence of skill can really enhance the value of the architect's work if the decorator does not carefully think out and follow those immutable principles which, whilst they allow of an infinite variety of treatment, have for their base the expression of the repose and stability of the architecture.

J. D. CRACE.

SAND FOR BUILDING.

TORONTO, December 21st, 1903.

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—In your editorial notes, November issue, you state that "a Company who are carrying out dredging contracts in Toronto are sending out circulars re Water Washed Sand (whatever that may mean) and are asking a higher price for their material, which is a waste product, etc.

As there are three misstatements of facts in your article and as the conclusions you draw are based on these misstatements we wish to have them corrected.

1st.—Our sand is not the waste product of a dredging contract but we have spent $20,000 to build special plant, including a twin screw steam barge to bring our material to Toronto docks and it is dredged solely for the purpose of the building and contracting trade.

2.—A higher price is not asked "for this material with the high sounding name." Experiments show that 1% of clay or loam in sand decreases the strength of mortar or concrete made with it 10%, and as most pit sands have from 2% to 6% of clay, loam or vegetable matter in it, the value of the cement or lime is decreased accordingly. Our water washing consists of pumping two thousand gallons of water per minute and discharging it over and through the sand so that any loam, vegetable matter or clay is washed overboard and the pure, clean, waterwashed sand only is retained.

It is uniform in quality, the grains being graded from fine to coarse. Tests made at the City Hall, Toronto, shew that cement made with it in three months time is 57% stronger than pit sand. Toronto is the only city on the Great Lakes that has not been using dredged sand for from ten to fifteen years past. Nothing else is used in Chicago, Fort William, Port Arthur, the Canadian Soo, Detroit, Windsor, Toledo, Cleveland, Buffalo, Hamilton, Montreal, Kingston and Ottawa.

Toronto architects have complained for years about the poor quality of some sands that have been brought on work executed by them, but there being no fixed standard they found it hard to get just exactly what they required.

Last year we fixed a standard by washing out all fine material and screening out all coarse material so that we get an even quality of goods every day, pure and clean.

Architects and many builders have been quick to see the merits of our standard sand and our trade has increased 350% for 1903 over 1902 or from 6000 cubit yards in 1902 to over 25,000 cubic yards in 1903,

Trusting that you will give this letter equal prominence to the article containing the misstatements.

Yours sincerely,

SAND AND DREDGING, LIMITED.

FIREPROOFING METHODS.

"A lie which is all a lie may be met and fought with outright;
'But a lie which is part a truth is a harder matter to fight."

To the Editor of the CANADIAN ARCHITECT AND BUILDER.

SIR,—In your December issue appears a letter from Mr. F. W. Barrett, Agent of the Expanded Metal Company, in which he purposes to print cuts showing the effect of fires in buildings of terra cotta arches, and of buildings of concrete construction.

Your correspondent starts out on his crusade by referring to the fire in Pittsburg, Pa., of May 1st, 1897, and selects for his demonstration the Horne Department Store, while ignoring all reference to the Horne Office building adjoining; the floors of the former being of dense tiles, the latter of porous material.

He states :—"The fire burnt out the woodwork and contents but was NOT HOT enough to destroy the stone work on the front; it WAS HOT enough to destroy the terra cotta floors throughout a great part of the building" (the capitals are mine).

When one considers that the building in question was a Department Store—6 stories and basement, filled with the usual stock of such stores, i.e., packing, crockery in crates, dry goods, etc., which were completely consumed; the intensity of the fire may readily be inferred.

In reply to your correspondent's assertion that the fire destroyed the terra cotta floors, I would refer him to the report of Mr. S. Albert Reed, manager of the New York Tariff Association, an authority, presumably unbiased; he says—"The collapse of the roof involved in more or less damage almost the entire half of the building east of the large wall"—"Now although FOUR-FIFTHS of the arches were standing after the fire, AND ONE COULD SAFELY WALK OVER THEM (if "Fireproof" of Chicago is right, it does not seem safe to do that on concrete floors even before a fire) there is nevertheless a damage throughout the building to the under side of these arches by the breaking and dropping out of the lower webs."

It has long been contended, that dense tile are not as good as tiles of porous material; and reference to the Horne Office building, wherein the floors were of the latter material and which came out with flying colours, again proves the claim good.

I await with interest Mr. Barrett's instances of concrete floors under fire: but in the meantime beg to call his attention to some very recent collapses of concrete floors, which probably deeming discretion the better part of valor, on being tested for strength, forthwith fell in, killing several workmen :—J. L. Mott Iron Works, Trenton, N. J., Ferro-Concrete, December 8th; Bellefield Apartments, Pittsburg, Expanded Metal, December 5th; Will & Bauman Building, Greenpoint, October, and several others as enumerated in the Fireproof Magazine.

Yours truly,

A. MULLER.

628 Carlton Ave., BROOKLYN, DEC. 29, 1903.

DECORATIVE CEMENT PRODUCTS.

BY CHARLES D. WATSON.*

In the history of the development and use of building material the nineteenth century might well be termed the experimental age of Portland cement, but the beginning of the twentieth will surely mark the age of cement construction. Bridges, foundations, pavements, viaducts, tunnels, breakwaters, piers, reservoirs and houses are now being built of cement

DETAILS ON IVEY WAREHOUSE AND ST. CATHARINES LIBRARY.

and its rapid advancement bids fair to fulfill what once seemed a marvellous prediction that "the house of the future will be poured or moulded in forms and the average man will select his house from standard designs as he now selects his furniture." What has long been called the building material of the future has become the material of the present.

No small portion of this rapid development of uses of Portland cement for building has been the advancement made in the manufacture of plain and ornamental cement stone.

That stone was manufactured long before the records of history is shown by the discovery of artificial stone vessels in the ancient ruins of the prehistoric mound builders. Their stoneware is supposed to have been made by pulverizing lime rock which when moistened with water, was moulded into the desired shape, set in the sun and being continually sprinkled with water the chemical action took place, the vessel became hard and at last formed a stone which has stood the test of ages and remains to-day as a striking example of the durability of cement products.

We have plenty of evidence that the Romans knew the value of concrete and wherever they have employed it in building it has demonstrated its superiority over natural stone under similar conditions. The whole of the dome of the Pantheon with its 142 ft. span is of cement concrete. The inside lining of one of the Grecian temples is of cement concrete, while the facing was of stone ; the latter has long since given up its struggle with the elements, but the concrete which was intended to play the minor part stands as smooth and solid as when made. A Roman aqueduct lined with cement built in the first century has been preserved in perfect condition for the past twenty centuries.

We have reason to believe that even the pyramids which have so long stood as an example of the marvelous work of a race who could perform feats in engineering that no man is able to explain, are made merely of separate blocks of concrete.

From the fall of Rome until the dawn of the nineteenth century the use of cement was apparently little known except for cement mortars. With the discovery of Portland cement a material was again produced which made satisfactory concrete and from that time to the present day cement stone has made rapid progress, especially in Europe, where it has reached a high stage of perfection and takes high rank among the industries of England, Germany, France, and Belgium. In the year 1902 one firm alone in Germany manufactured $1,080,000 worth of cement products including plain and ornamental building stone, sewer pipe, statuary, park ornaments, etc. The company have four large plants and employ an average of 2,500 men per year. In many parts of England cement stone is extensively used and large plants are now engaged in its manufacture.

The use of cement stone in America has until recent years been less marked, due in great part to the abundance of other cheaper building material. The last decade has shown a remarkable advancement in the manufacture of stone. One of the oldest examples of this construction is the house of W. E. Ward at Port Chester, N. Y., built a quarter of a century ago and which stands in perfect preservation today. Perhaps the earliest work of any magnitude were the great hotels of

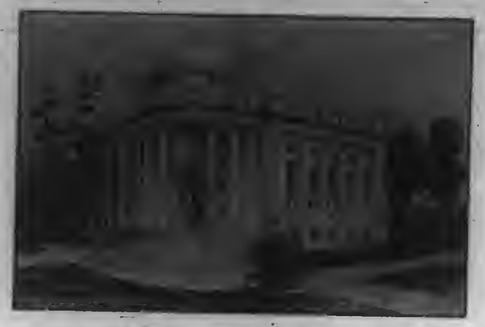
WAREHOUSE, WELLINGTON STREET WEST, TORONTO.

Florida and California and the Pompeiia at Saratoga, N. Y. Many difficulties were met in cement construction in its early stages through ignorance of the use of Portland cement and this class of construction gained for itself the name of being very unreliable. Continued experiments and improvements in methods have to a great extent offset this feeling until now it can safely be said to be a thoroughly established enterprise which is destined to work a revolution in building construction. The business has increased from a few isolated

*Chief Engineer Roman Stone Co., Limited, Toronto, Ont.

factories scattered about the country until now it is almost impossible to find a city of any considerable size without its cement stone factory. Some cities have a plant to every 40,000 inhabitants and judging by the present rate of increase cement stone factories will soon be as plentiful as brick yards.

All of the larger Canadian cities have artificial stone factories of some kind, but undoubtedly the largest and



CARNEGIE PUBLIC LIBRARY, GUELPH, ONT.—BUILT ENTIRELY OF ROMAN STONE.

best equipped is that of the Roman Stone Co., of Toronto. This plant has been in operation for a little more than a year and has in that time turned out a considerable quantity of very creditable work. Their plant is a model of its kind being equipped with pattern shop machinery, stone crushers, grinders, and screens, dryer, mixer, traveling cranes, and hot air blast heating.

The company is manufacturing under the patents granted to C. W. Stevens for the cement stone known as Litholite. The patents are broad and cover the manufacture of cement stone by casting concrete in a sand or other absorbent mould. The patent is about five years old. The process while very simple gives the ideal conditions for making cement stone. The concrete mixture made of Portland cement and ground stone of many different sizes is poured in a semi-liquid condition into a sand mould exactly as melted iron is cast in a foundry. The patterns are made the exact shape, size, and finish of the stone required and moulded in the sand, no allowance for shrinkage being required. As soon as the concrete material comes in contact with the sand the water filters off, leaving the cement stone in plastic condition with just enough water to produce perfect crystallization. The process is quite similar to the method of preventing settlement in loose earth fills by puddling with excessive water. No amount of pressure or tamping by hand or machine can make a stone as compact and homogeneous. Proof of its great density is shown by its specific gravity which is about 90% of the stone of which it is made, the loss of 10% being in all probability due to the difference in weight of the cement and stone. The process bears a marked resemblance to the method by which nature has produced our best building stones, i.e. by the depositing of sand in water. Nature has cemented her stone by the action of heat and great pressure, but Portland cement accomplishes in a short time what requires ages by nature's method.

The great feature of the process is the absorption of the water by the sand which surrounds the cast. This sand retains the moisture and acts as a wet blanket to nourish and feed the cement with just sufficient water to produce perfect crystallization. The process produces a stone absolutely uniform in color where heretofore cement stones have always had the drawback of having a dark and spotted appearance of the surface when made in rigid moulds. Most cement stone has to be painted or coated to give it a suitable color for decorative purposes in high class work. The question of methods for obtaining presentable surfaces to concrete work has baffled the engineering profession for years—all cement washes or paints having long since been discarded as only temporary improvements. Stevens' process has solved the mystery and produces a stone so closely resembling nature's product as to deceive the experienced eye upon the closest examination. It enables one to reproduce any desired finish that can be obtained in fine cut stone and at considerable less expense. It has a much finer appearance than terra cotta, and unlike it or any other cement stone admits of fine hand carving; being of so uniform a texture and without cleavage it is impossible to distinguish the hand worked from the cast faces.

The stone used by the Toronto company is nothing but the best selected building stone. For white stone Niagara lime-stone and pure white marble are used; for gray, brown, red, and olive similar colored sand stones are used, thus avoiding the difficulty heretofore found in the fading of the colors used in making cement stone.

The stone upon the arrival at the plant is carefully inspected and all unsound material rejected; if found to be dirty it is thoroughly washed and then dried in a large rotary drier. It then passes through the crusher

EXAMPLES OF ORNAMENT.

and grinder from which it is carried by the conveyor and elevator to the rotary screen on the second floor. This screen is provided with three different sizes of mesh which separates the crushed stone into three different sizes, each of which is deposited into an individual bin; these bins together with a cement bin are located on the first floor directly over the mixer. When making a

mix of cement and stone a definite amount is taken from each of these bins, the quantity depending upon the purpose for which the stone is intended to serve and governed by certain rules determined by continued and careful experiment to obtain the best results. This grading of the crushed stone is, beside the careful selection of the cement, one of the most important factors in the manufacture of stone. It has long been recognized that great care should be taken in this particular. Many concrete and cement stones are made by merely mixing a little sand and gravel or crushed stone with cement in certain proportions, no attention being paid to the size of the grains of the sand or gravel. Such work combined with lack of knowledge in selecting and

FACTORY OF ROMAN STONE COMPANY, LIMITED. TORONTO, ONT.

handling cement has caused cement products to be regarded with undue suspicion.

After the cement and stone have been thoroughly mixed dry in a mechanical concrete mixer the water is added, not by the usual method in mixing concrete, but water which is kept at a constant temperature and the quantity automatically measured. In this way absolutely uniform results are obtained.

The ingredients are then thoroughly mixed wet for five minutes and run off into the agitator or ladle. This agitator is a large tub or barrel fitted with spiral paddles which are continuously revolved to keep the mix uniform. The agitator is carried about the foundry by a travelling crane of which the plant has three all equipped with two ton triplex hoist. The cement mixture is poured into the moulds through a funnel and T pipe to keep it from cutting through the sand moulds. After the casts are made the stone is allowed to remain in the sand from three to four days when it is removed to the storage shed and carefully finished, all necessary precautions being taken to insure perfect results.

While the proper munipulation of the cement and careful observance of certain laws are necessary for producing the best product, yet by far the most important factor in manufacture is the selection of the proper cement. While nearly all architects and engineers realize the importance of proper testing, yet it does not seem to be universally known that a cement may satisfy one or several conditions yet fail in the special use for which it is intended; thus cement has been selected for use in making stone that stands the highest test and was universally recommended by professional men experienced in the handling of cement, yet imperfections have resulted that caused distrust on the part of the user and no end of annoyance to the manufacturer. It does not follow that any cement will give satisfaction for the manufacture of stone. However cement casts for building purposes have been manufactured in Europe for years and we find that these difficulties in manufacture have, by the aid and research due in a large part to the Association of Portland cement manufacturers, been successully overcome, where satisfaction is guaranteed and the industry can safely be said to have passed the experimental stage and stone is produced which in many ways excels the natural product.

The crushing strength of Roman Stone at the age of 6 months has been found to be from 2000 lbs. to 4000 lbs. per square inch depending upon the material used. All stone subject to tensile stress is carefully reinforced with steel. Stones as long as twenty feet have been made in one piece at the Roman Stone Company's plant and single piece columns are sold at a price little in excess of what the same would cost in wood.

The officers of the company are well known Toronto men who have been prominent in the promotion of some of Canada's most promising industries: Lt. Col. H.M. Pellatt is President, Hugh Blain, Vice-Pres; A. E. Ames and Col. James Mason are Directors with G. P. Ames as Manager.

HELP WANTED

Draughtsman — Young Man with ideas as Assistant in designing Gas and Electric Fixtures. Box 25 care ARCHITECT AND BUILDER,

CANADIAN

Contractors' Hand Book

AND ESTIMATOR

The third edition of the Canadian Contractor's Hand Book is now on sale. The book has been revised and enlarged to upwards of two hundred pags, and the title changed to the Canadian Contractor's Hand-Book and Estimator, considerable matter bearing on the cost of performing various kinds of work having been added.

The price of the third edition, mailed free, is $1.00 to subscribers of the CANADIAN ARCHITECT AND BUILDER, and $1.50 to non-subscribers. Order from the publishers,

EXAMINATION TO QUALIFY FOR ASSOCIATESHIP

—IN THE—

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The Royal Institute of British Architects desiring to give facilities for those in the Colonies to qualify by examination for associateship in the R.I.B.A., will hold the fourth examination from June 24th to July 1st, 1904, in Montreal. Applications, fees and probationary work must reach London by the first mail arriving after April 9th, 1904 Intending candidates who must be not less than 25 years of age, can obtain application forms and copies of the previous examinations on application to

ANDREW T. TAYLOR,
Hon. Sec. R. I. B. A. for Canada,
North British & Mercantile Building,
60 St. Francois Xavier St., Montreal.

All who are full members of the Province of Quebec Association of Architects and the Ontario Association of Architects by examination, are exempt from probationary work.

NOTES.

We may well ponder over the fact says the London Builders Journal, that Sweden sends us yearly £300,000 worth of setts and kerbs, manufactured goods, duty free. We may well think over the significance of this, and bear in mind, as an example, that the Dartmoor quarries have lost a considerable portion of their trade in these setts and kerbs because Norwegian quarry-owners can pay their workmen less money and send their finished material into our ports without paying any duty on it.

THE LATE MR. J. F. PEACHY.

Mr. Peachy, who died at Quebec, his native city, on the 31st December last, aged 73, was first a pupil of the late P. Gauvreau, local Government Architect for many years, and then studied for some time under, and was partner of Mr. Chas. Baillarge, Architect.

During his professional career he erected, after its destruction by fire in 1882, the Parish Church of St. Jean Baptiste, of which Mr. Baillarge had fathered the first edition in 1854. Prof. Haire, of New York, considered that the interior of this edifice, due to its height and light and the elegance of its proportions, compared favourably with the New York churches.

Mr. Peachy was the architect of the RR. gentlemen of the Seminary of Quebec, whose chapel he re-built, after its destruction by fire, and also what is called "Le Grand Seminaire," uniting the old Seminary to the University Buildings, erected under Mr. Baillarge in 1854.

The subject of our notice also designed the new Cathedral and the Seminary buildings at Chicoutimi; the interior of the church of N. D. de Ste Anne de Beaupre; the church of N. D. de Lourdes at St. Sauveur, together with numerous buildings, including chambers, presbyteries, school houses, private residences, as well in many of the parishes of the Province of Quebec as throughout the city itself.

Mr. Peachy was, for some 20 consecutive years, a representative of St. John's Ward, Quebec, in the City Council, becoming in time president of the road and then of the Water Works Committees.

He was one of the church wardens for the Parish of St. Jean Baptiste; for some years the president of the school of Arts and Trades, which had its rooms in a very nice building, designed by him, on St. Joachim St. He was a past president of the Province of Quebec Association of Architects.

The late Mr. Peachy was, in every respect, a man of ability and unimpeachable charatcer.

BY THE WAY.

I am pleased to note the protest entered by the Builders' Journal of Baltimore against the proposal to build in New York a six-storey school with accommodation for 4,500 pupils. Emphasis is laid on the danger to which the children assembled in such large numbers would be exposed from fire and disease.

× × ×

The New York Electrical Review has a word to say to architects and builders on the desirability of providing an abundance of outlets when wiring a house for electric light. Dark corners should be avoided, and provision made to light when required every part of the house to which access may be desired without the necessity of resorting to matches and kerosene lamps.

× × ×

The story is told of an Australian missionary in China who was endeavoring to convert one of the natives. "Suppose me Christian, me go to heaven?" remarked Ah Sin. "Yes," replied the missionary. "All right," retorted the heathen, "but what for you no let Chinaman into Australia, when you let him into heaven?" "Ah," said the missionary with fervor, "there's no labor party in heaven."

One brick never built a house, neither will one ad build a business.

The famous leaning tower has changed owners. It seems there was a lien on it.—Toronto World.

The sudden death of Mr. Samuel Coulson, general manager for Messrs. H. R. Ives & Co., Montreal, has occasioned wide spread regret. Mr. Coulson was suddenly stricken by heart failure while visiting at the home of his brother in Toronto.

LEGAL.

Mr. Legriel, a French architect, being dissatisfied with the manner in which one of his buildings was reproduced from a photograph in a scientific journal, called La Nature, instituted an action, charging that the reproduction was a forgery. The court dismissed the case. It was laid down by the judge that everybody had the right to reproduce a public way, and consequently the houses which were to be found alongside; moreover, a critic of art had the right to give evidence in his article by views which became graphic information and corresponded with literary quotation. Whenever there was an abuse the judge could intervene if called on.

NOTES.

Mr. William Fraser, well known to Toronto architects as a quantity surveyor, has been appointed the representative in Toronto of the Gilmour Door Company, Limited, of Trenton, with office at 49 Yonge Street Arcade.

The most beautiful colored sheet-glass is made by the French and Belgian manufacturers, such as sheets composed of two layers or coats of glass, white and colored, and in some instances sheets made of white glass, and covered over with as many as four different layers of colored glass, put on very thin, and equal in thickness on the whole of the surface. For the coloration of this glass, as for all colored glass in general, the oxides of the different metals are used. For blues the oxide cobalt, or zaffer. For the different shades of blue, different proportions of cobalt. For a very light shade of blue for spectacles, a mixture of cobalt and red oxide of iron. London smoke is obtained by a mixture of the oxides of copper, iron, and manganese. A black is produced by increasing the proportions of these three oxides. Purple glass has for coloring element oxide of manganese. A glass so colored and made with soda gives a purple shade, edging on the red, while a potash glass will give a bluish purple. This color is made of a deeper blue by the addition of cobalt. The brown purple is made with a mixture of oxide of manganese and oxide of iron. The purple of the ancients can be perfectly imitated with a mixture of oxide of manganese and red oxide of iron.

Students' Competition.

The report of the Committee of Award is printed in this number.

The sixteen sets of drawings received in this competition have been placed on exhibition in the rooms of the Ontario Association of Architects, 96 King Street West, Toronto, and will afterwards be exhibited in the office of the CANADIAN ARCHITECT AND BUILDER in Montreal.

An Important Decision.

The Supreme Court of Massachusetts, has recently decided that when an insured building is destroyed by fire and cannot be replaced except at a cost greater than that of the original structure, the companies holding the insurance policies are liable for the difference. This decision applies to general policies of insurance in which the limit of liability is not specifically stated. There are two remedies open to the insurance companies: either to limit the liability in all policies, or charge stiff rates on all but buildings constructed on fire proof or fire resisting principles.

Elevators in Factories

The Toronto Chapter of the Ontario Association of Architects will ask the Provincial Government to make certain amendments to the provisions of the Ontario Factories Act governing the installation and operation of elevators in factory buildings. Section 51 of the Act adopted 1901, provides that elevator shafts in factories shall be provided with automatic hatch doors. The increased speed at which elevators are required to travel to meet modern business requirements renders the use of hatch doors impracticable, and they are found to be not only a nuisance but unless used with gates, dangerous.

Effect of the High Cost of Brickwork.

Already there seems to be trouble in sight for the building trades in Hamilton. The bricklayers of that city have intimated that they will demand 50 cents per hour next season. As a result less building will probably be done and in buildings that may be erected, the use of brick will as far as possible be avoided. The high cost of brick-work should tend to hasten the introduction of cement for the construction of the walls as well as foundations of buildings. It is already apparent that for this and other purposes cement is destined to be extensively employed in future building operations.

The Baltimore Fire.

The tremendous destruction of property resulting from the Baltimore fire is conclusive evidence, that modern fire fighting appliances and methods of fire proofing buildings are of little avail to check or subdue a fire that has once gained headway under untavorable weather conditions. Architects, insurance and municipal authorities and building owners will await with much interest the reports of experts, which we hope will shortly be forthcoming, showing the behaviour during the conflagration of buildings of supposedly fireproof construction. Meanwhile there will probably be an influx of architects into Baltimore in search of information and commissions.

C. A. & B. STUDENTS' COMPETITION FOR A PUBLIC LIBRARY FOR A SMALL TOWN.

Report Of Committee Of Award.

The Committee in presenting their award and criticisms, wish to express their appreciation of the generally high character of the designs submitted. They consider, however, that the majority of the competitors might have made themselves more familiar with the requirements of a library and particularly of the working requirements of a library of the small size described in the conditions. As regards the criticisms appended, it might be said that the designs other than the first four are not placed in the order of merit.

The committee award the first place to the design by "Ionic," second place to the design by "Mic," third place to the design by "Napsugar," and honorable mention to the design by "L'Avenier."

A. F. Wickson

A. H. Gregg
} Committee.

[The names of the successful competitors in this competition are: "Ionic," Mr. Edgar Guy, 8 McMaster Avenue, Toronto; "Mic," Mr. Louis Labelle, 136 Parc Lafontaine, Montreal; "Napsugar," Mr. Clarence Thetford, 237 Dufferin street, Toronto; honorable mention, Mr. L. Van Egmond, 508 McKinnon Building, Toronto.]

Below will be found individual criticisms by the members of the Committee of Award of a number of the drawings submitted in the competition:

"Ionic."—(1st prize)—In this design the author has shown an understanding of the character of a building called for in the competition. The elevations, broadly considered, express the purposes of the building by their effect of scholarliness, simplicity and repose, developed from a plan in which the same qualities are to be found.

Criticising in detail: the plan is laid out on simple lines, and apart from the technical requirements of the building, is excellent. There is a thoroughly monumental feeling in the treatment, the axes are well considered, while every room is well proportioned, and asserts its purpose unmistakably.

The entrance steps are a good preparation to the vestibule, which is of suitable size and proportion. The rotunda as the author names it, forms a useful and interesting centre to the main portion of the building.

Considered from the standpoint of the Librarian, however, the plan is open to severe criticism. The element of administration and supervision has been almost entirely ignored; in fact each reading room forms an independent unit, and is not related distinctly enough to the main sources of inspection and supervision. This might be overcome to some extent by placing doors into the catalogue and librarian's rooms, or by arching between one or more of the bays in the walls between the rotunda and the reading rooms.

The reading rooms are properly lighted as also is the stack room.

The elevations are well handled, the general proportions being good, and the features carefully treated. The entrance is well marked, and the detail in connection with it is appropriate.

The wash work of the elevations is rather undecided, but the line work is excellent, firm and authoritative, and the detail is indicated with wonderful clearness and accuracy.

"Mic"—(2nd prize)—In this design the plan and elevation both lend themselves to the unrestricted building boundaries of a small park, such as would be found in a small town.

The plan is simple and is good for these reasons, viz:—liabrarian is in close touch with stacks, is easy of access and commands an almost unrestricted view of reading room. The defects in the plan are: 1st, the ladies' toilet room is too prominent and the men's not sufficiently so, being beyond the control of librarian. A sine qua non in small library building is that everything must be under the supervision of the one attendant. 2nd, the stairs should be from stack room so that books may be brought up direct: there should also be an entrance to the stairs so that books received in cases may be taken down to the "work" room which should be in the basement under the stack room. The grouping of external features is somewhat marred by the competition between the gable and the tower. Instead of two separate windows with a mullion under the arch of each a mullion window extending the length of both of these openings would possibly have been an improvement. The choice of rubble walling was good. The rendering is exceptionally good.

"Napsugar."—(3rd prize)—This is a fairly well conceived plan with the exception of the Committee Room appearing to be inserted more to fill a vacant space than a requirement of the library. The attendant has fair supervision of the reading rooms from the desk, but not as much as would be desired. The entrance is very effective and proportionate. The elevation is well conceived and well rendered. It's weakness is the rather wide spacing of the columns to main entrance and the poorly proportioned windows with their rather cramped arches which form the principal features either side of the entrance.

"L'Avenier."—(Honorable Mention)—This design in the French Chateau style shows careful study and much merit in rendering as well as design. The ink drawing of the side elevation is particularly effective. As regards the plan, a great improvement could be made for the general convenience of the building had the delivery desk been moved forward to line with the rear wall of the main building and the vestibule projected forward to correspond; in this way the view of the reading and news room from the delivery desk, which has evidently been considered, would have been much more effective. As to the exterior, it would seem as if there are rather too many features in the front for a building of this size. The general effect of this drawing would have been much improved had the lettering been less obtrusive.

"Tacks."—The author has apparently not given very thorough study to the problem in regard to the plan—the accessories of Lady's Room, Magazine Room as also Board Room, for which the Librarian's office would adequately answer, being added more for their external effect than for their necessity to a library of such small requirements. The one attendant who is all that such a small library could be counted on having, is not given a good oversight over the reading rooms by reason of their entire separation from the counter.

The conception of the elevation is fair, but the detail is not so good, while the rendering, particularly of the front elevation, is very feeble.

"Number 4"—This design is a very pleasing conception for a library building of the required size both in plan and elevation. The stack room is rather poorly lighted and the reading room would have been better separated from the delivery by a screen, in order that the attendant might have full view of it from the counter. The plan is somewhat extravagant in the amount of wall taken to enclose so small an area. The elevation is very pleasing and consistent, its chief defect being the window in gable having its label mould round and its upper part apparently filled with solid stone work. The rendering while somewhat effective is rather indefinite.

"The Last."—In this plan the accommodation for books in the stack room seems inadequate and it has the great objection that there is no simple method which could be adopted to enlarge the room without impairing the appearance of the building. If the stack room had been placed in the centre of the rear, it could then have been extended indefinitely at any future time without affecting the general design. The space given for delivery of books would be found small and the librarian or attendant has no way to enter the stack room, except by opening up the delivery desk which would be extremely awkward. It would be almost impossible according to this plan for the attendant in charge to have any supervision to the reading rooms. As regards the elevations a most objectionable feature is, in the building of a classical character, to have windows inserted of a design more suitable for an Elizabethan residence and the main entrance door also is hardly in keeping with the rest of the design. The heavy projecting cap to the base course is a detriment; a better scheme would have been to have made a slightly projecting course under the columns and the plinth at the ground level course. The rendering is fairly good but more care should have been taken, particularly in the elevations, to indicate detail, such as the balusters and parapet and the consoles of the main cornice. If the author of this design compares these details with any standard examples, he would see how defective they are. The lettering in this design is also rather sketchy for a competition drawing.

"Kohinoor"—The general conception of this building is suitable for its purpose. There is an attempt to make a good plan, but the plan is defective in that the delivery room, between entrance doors and counter, is too cramped in comparison with the vestibule, and in that the rear ends of the reading rooms do not adequately balance the front end of these rooms. This latter awkwardness has arisen in attempting to make a symmetrical side elevation enclose an unsymmetrical plan. The plan of the front wall and stack room are much better. The arrangement is suitable for the working of the library but the stack room is about 40% too large for the volumes specified. The elevations are good, being, relatively, much the better part of the work. Larger paper with line borders would have greatly improved the appearance of the drawings. A margin of ¾" on one side of a sheet and a full 2" on the other side is an injustice to a drawing. The mechanical line work of the rendering is fair, but there is great room for improvement in the freehand work. The washwork of the surroundings of the building shown on front elevation could be very greatly improved. A safer method for one with "Kohinoor's" experience would be to show the rendering of trees in large masses after the manner of "Mic."

"Max" is a good design in some respects but is more suggestive of a court-house than of a library. The plan is defective in the following particular: From the side elevation one would have expected a room the whole width of the wing, as the central window is the the largest of the three, but, on consulting the plan, we find two rooms across the end—a reading room and a lavatory—with unequal sized windows in the end of the reading rooms. "Max" should not have erred in this, as the rest of the work, especially the handling of the dome, shows better knowledge. The elevations are good, but the spacing of the columns at entrance could be improved. The line work of wash drawing is fair, but the brush work shows evidence of haste.

"Queen City."—The general conception is much more complicated than was implied in the conditions. No mention was made in the programme of art museum or of librarian's apartments. The plan lacks in pronounced architectural character, which the problem permitted. The stack room is badly lighted. Supervision of reading room by attendant at lending desk is impossible. Elevations are stiff. The large windows in the side elevations are poor and badly out of scale with the rest of the work. Arrangement of drawing is fair. Rendering is hard and the clouds are badly drawn and would have been better omitted.

"Rex." The plan is poorly handled. The main object seems to have been to get a central circular hall for delivery room at all costs. One would have expected a circular motive in the roof over this delivery room instead of a square one as indicated. The plan of the stack room is bad as the side of it is bowed to the right merely because the rotunda wall projects into it at the left, and because the windows are put in to balance the reading room windows on the elevation instead of to properly light the stacks. "Rex" has erred in thinking a reading room and stack room may, logically, have the same external expression. The entrance is the best part of the whole plan, but sliding doors in same are not practical. The stair to basement is badly handled. The general effect of the elevations is better than the architectural detail and rendering. A good honest line drawing is much better than "Rex's" spotty and indefinite method of rendering. Fewer surroundings and the omission of badly drawn figures would have been safer in the case of one with his experience.

"Ha Ha."—The design has the merit of simplicity, and the desire to give the building the character a Library ought to possess. The plan, while it is formal in general outline lacks that recognition of axes that is essential in work of a monumental character. The attempt to secure complete supervision is successful, but on the other hand, the stack room is poorly lighted, and the lavatories are badly situated.

The design would be more successful if brought into harmony with good monumental work both in planning and elevation and if more study were given to proportion and detail.

"Utility"—"In this design the librarian is too far from stack room and has not a sufficient supervision over the reading rooms. There should be a room in connection with the stack room either on the same floor or in basement for "mending"; the plans are carefully drawn. The elevations would bear more study; the omission of a frieze and the enormously large windows are detriments; the design would have been better with less ornament; the parapet as well as the wall below lacks continuity. The idea followed in the rendering is not at all bad.

"Alpha."—The author of these drawings has produced a design which calls for much praise, and which possesses a great deal of interest and charm arising from the directness and ingenuousness with which he has handled the subject. The general treatment however, both in plan and elevation seems inadequate for the purposes of the building. The reading room, containing as it does, accommodation for all the readers, men, women and children, and for the books and catalogues as well, is hardly appropriate in a library of 10,000 volumes, although it must be acknowledged the matter of supervision is much simplified.

The elevations are simple, direct and effective, and like the plans are unpretentious. The rendering has may good qualities, is unaffected and appropriate.

"CAMBRIA."—This library possesses the merit of being one which could be built at small cost. The elevations are below the average both as to design and rendering. The arch over front entrance is weak in appearance. The stack room should have direct light for all the aisles between the stacks.

"MONU MENTAL."—This design has been conceived in a somewhat extravagant spirit, the stack room being very large in area for the accommodation obtained. The attendant at the delivery desk has practically no supervision of the reading rooms, and the catalogue and reference room rather fills voids in the plan, than composing well with the workable arrangement. The dome as shown in elevation is inadequately expressed on plan. The elevation is extravagant in conception with the dome superimposed without adequate reference to anything underneath it. The elevations are rather crudely rendered, the accessories such as sculpture, carving and landscape, being rather bad.

"TOUT A VOUS."—"Tout a Vous" has a good plan, the main defect being the Librarian's obstructed supervision of the rooms (see criticism of "Mic.") The connection of the reference room with stack room was well thought out. It is questionable whether a recreation room would be of any service, as being entirely away from the attendant there would be great difficulty in controlling the frequenters. The proportions of the exterior are satisfactory and the general design is good, though the running of the large piers up through the cornice creates a lack of cohesion at that part and the arches over the cornice above the small windows is very unsatisfactory. The rendering of the side elevation is rather better than that of the front; the printing is neat. The drawings would have looked better with a more liberal amount of paper.

MR. JOHN GEMMELL,
President of the Ontario Association of Architects.

"MONSIEUR."—"Monsieur's" plan has much to commend it, the position of the delivery and reading rooms being generally speaking, well arranged with reference to Librarian's desk and the stack room has the necessary mending room easily accessible. The plan is a little pretentious for a 10,000 volume library, and had it been curtailed, bringing the stacks closer to the attendant, it would have been a better plan. The elevation having so much blank wall space would have been improved by having a better proportioned cornice. The outline of the dome could be improved—in fact were the author to set up a perspective he would be surprised at the manner in which the dome would disappear. It would have been better to put windows in the reading rooms at the front and the windows in these rooms should have had their sills much nearer the floor.

"CRESCENT."—The author of this design disregarded one of the rules of the competition which states that drawings are to be made to an eighth scale. The plans in this design are presumably to a sixteenth scale, although no indication is given by which this may be determined. Generally speaking the plan and elevation have much merit and the author would have done well to have given a little more study in order to bring them to greater perfection. This plan has the defect of others in not giving the librarian in charge sufficient command of the reading rooms. Too much space has been devoted to stairways and we think it would have been better to have enlarged the floor area of the stack room to make it more in keeping with a building of this size. The general proportions of the front elevation are very good, but the rendering exhibits too much haste. The two single trigylphs over the columns at the entrance would be better omitted. With more care in the details and general rendering, this design would have stood much higher on the list.

"REX NO. 2."—This competitor, as stated in connection with his drawings, is a student of only eleven months standing. Quite apart from this fact the design is worthy of great praise, and in view of the draughtsman's short experience is really remarkable.

The design as a whole bears the stamp of its purpose, is quiet and dignified, and of good working quality.

The plan is handled in a thoroughly monumental manner. The treatment of the approaches, entrance and rotunda are excellent. The plan would be much improved, considered from a strictly architectural standpoint, if the size and position of the librarian's, and catalogue rooms, &c., were altered, and the centre line of the wings horizontally were made the axes of the reading room.

The stack room is well planned in its arrangement and lighting. Technically speaking the element of supervision has been well worked out.

The elevation is very good indeed in respect of its general design and proportion, but it is undecided in detail. The treatment of the entrance requires more study, as also does that of the windows, but the work as a whole is on right lines.

The rendering, while it shows inexperience, is quite acceptable. The background of trees is simply but effectively indicated.

[EDITORS' NOTE.—The publishers of THE CANADIAN ARCHITECT AND BUILDER wish to express their satisfaction with the result of this competition, as well as their thanks to the Committee of Award for the time and care bestowed upon the work of the competitors.]

ONTARIO ASSOCIATION OF ARCHITECTS

PROCEEDINGS OF THE ANNUAL CONVENTION.

The President: Mr. W. L. Symons opened the Convention by calling on the Registrar to read the minutes of the last Annual meeting. The Registrar explained that as the published proceeding gave a detailed report of all that transpired the minutes had been shortened as much as possible.

Mr. Gregg then read the minutes which were adopted.

The President's addres followed.

PRESIDENT'S ADDRESSS.

Members of the Ontario Association of Architects in your 16th annual convention assembled:

In my address to you to-day I shall not dwell on the growth and work of our Association during the past year, as you will have evidence of these in the various reports to be presented to you this afternoon, the discussion of which will fully bring into view our year's progress. Truly our own affairs are of the greatest importance to us as an Association; but there are matters that concern us, taking issue in the world about, of which as architects we should take a much closer view than we are inclined to, under the strain of our ordinary business responsibilities.

A succession of prosperous years has probably reached the climax in 1903. This year has been of unexcelled prosperity in our Province and throughout our Dominion. Every branch of trade, without exception, has enjoyed a measure of expansion beyond expectancy. New industries have sprung into being, older ones have greatly developed, and on every side the results of good times are seen. The trades and manufactures with which we most closely come in touch, have probably never had such demands for their products, and in some instances contracts had almost to go a-begging.

Yet all this abundance and prosperity has left unanswered some questions at issue for years, which we promised that when the good times came, and with them ease, and time to think, some of these grim intruders to our feasts would be dealt with.

The most unsettled question which concerns the interest of Ontario to-day is undoubtedly the labor question. All remember the strikes last spring between the painters, carpenters, builders' laborers, marble cutters, steel erecters, and their respective employers. In fact, almost every branch of the trades with which we as Architects come in contact in a business way, was severely disturbed.

It is not necessary for me to dwell on the value of the work unproduced, or figure to you the loss to the workers or employers, or the loss to the public through the unfortunate disagreements, but instead to endeavor to propose a remedy, or at least to ascertain what other communities have done under like conditions.

The Legislature of New Zealand, in 1894, passed "The Industrial Conciliation and Arbitration Act." That law, which under the administration of the Minister of Labor, enacts that any society consisting of not less than two persons in the case of employers, and seven in the case of workers, lawfully associated for the purpose of protecting the interests of the employers or workers respectively, may register as an "Industrial Union."

The Act created Boards of Conciliation, as well as a Court of Arbitration, to which Unions became subject upon registration.

New Zealand, for the purpose of the Act, is divided into Industrial districts. Each district is given a special Board of Conciliation, which has jurisdiotion for the settlement of industrial disputes arising within that district only.

This Board consists of five, or such unequal number of members as the Governor may determine, elected for three years, the members being chosen in equal numbers by the respective unions of employers and workers in the district, and they appoint their own chairman. Industrial disputes of any nature may be referred to the Board upon proper application, and the Board is to carefully and expeditiously enquire into such disputes and all matters relating thereto.

The decision arrived at takes the form of an agreement, to which the disputants are made parties, and upon signature, is filed in the office of the Department of Labor.

In case the recommendation is not accepted, the whole matter may be referred within one month to the Court of Arbitration for final adjustment; if not so referred, then the Board's recommendation becomes operative and enforceable in all respects as if an agreement had actually been made.

The Court of Arbitration is composed of three members appointed by the Governor, one on the recommendation of the employers' union, one on the recommendation of the workers' union, the third being a judge of the Supreme Court, who acts as president. The members of that Court also hold office for three years.

The award of this Court is to be given within one month from the close of the hearing. If any party, on whom the agreement or award (as the case may be) is binding, commits a breach of the agreement or award, the Court has the full and exclusive jurisdiction to enforce the same, as provided in the Act.

The Act also particularly provides that when an industrial dispute has been referred to the Board of Conciliation neither party to the dispute shall take part in anything of the nature of a strike or lock-out, but the relationship of employers and workers shall continue uninterrupted by the dispute. Any persons not observing these provisions of the Act can be treated as offenders.

That Act seems to have been generally accepted, as we find that the number of disputes adjusted under it during the first six years of its operation amounts to 205, of which 44, or over 20 per cent., relate to building trades.

In the year 1901, 103 awards were made, of which 16 dealt with building trades; in the year 1902 the number increased to 225, of which 30 were in the building trades. The returns for 1903 will show a still greater increase of references, thus showing the popularity of the measure.

In 1901 the New South Wales Legislature appointed a Royal Commission to examine into the labor dispute question generally, and Judge Backhouse, who was made one of the Commission, in his report says:—

"The Act so far has been productive of good; it has prevented strikes of any magnitude, and has, on the whole, brought about a better relation between employers and workers than would exist if there was no Act. It has enabled the increase of wages, and other conditions favorable to the workingman, which under the circumstances of the Colony they are entitled to, to be settled without friction and bitterness of feeling which otherwise might have existed. It has enabled employers, for a time at least, to know with certainty the conditions of production, and therefore to make contracts with the knowledge that they would be able to fulfil them; and indirectly it has tended to a more harmonious feeling among the people generally,

which must have worked for the weal of the country."

And the learned judge ends a very exhaustive report by saying:—

"Whatever may be the result, the world owes a debt of gratitude to New Zealand for having undertaken the task of demonstrating whether it is possible or not to settle industrial disputes by compulsory arbitration."

Enactments bearing upon this subject were also passed in South Australia in 1894; in Western Australia in 1900, and in New South Wales in 1901, but up to this writing I have been unable to procure copies of those Acts.

In July of last year a bill was introduced in the Parliament of the Commonwealth of Australia, based upon all the Acts mentioned, which however is not yet law. That bill dealt with the matter possibly in a drastic manner, by giving initiative powers in the public interests to the President of the proposed Court of Conciliation, who would be a Justice of the High Court of Australia.

Comment on this bill would not be pertinent at this stage, and I only mention it as showing the importance which is being attached to the problems in the antipodes. I may be pardoned, however, in mentioning the point, which is shown up clearly by that bill, namely,—the existence of a third interest, being that of the public, which is not always borne in mind in the discussions.

In Great Britain, as far as I can ascertain, labor disputes are dealt with by what are termed "Permanent Voluntary Boards," those bodies are organized in any labor district, and can consist of any equal number of representatives elected for a term of years from among the workers and employers interested, who, together, elect a chairman.

Such organizations are not in any way under the Government control, or of the federation of either labor or employers, thus acting entirely independent of both. After the hearing of the case an agreement is drawn up embodying the terms reached, which, if accepted, is signed by the parties interested, and which does not require the consent of unions.

During the year 1902 some 678 industrial disputes were successfully dealt with in Great Britain by this means.

Attempts have been made by the Ontario Legislature to find a remedy, but those attempts have hardly been met in the spirit in which they were passed.

As far back as 1873 "The Trades Arbitration Act" was passed, and again in 1890 "The Trades Dispute Act." Both laws, I understand, are still in force. Why they have not been taken advantage of is hard to say. They are certainly voluntary in their character; and if Voluntary Boards are feasible here as in Great Britain, the suggestion of their foundation is to be found in those Acts. I would point out, besides, that Voluntary Boards were always available, and needed no impulse from the Legislature; yet though that impulse was given, no heed was taken of it. When two parties to a dispute want to agree, then a means of settlement can readily be found; but apparently in nearly every instance within our memories the desire to settle has been absent, attributable, possibly, to outside influences.

In 1902 the "Trades Dispute Act" was amended by giving the Registrar of Labor an opportunity of intervening in disputes upon request; and it is pleasant to notice that in that and the following year some 25 troubles were settled in this way—but none of them in connection with the building trades disputes in Toronto last spring.

A bill to create a Provincial Board of Conciliation and Arbitration was introduced into the Legislature of Ontario last May by the Minister of Labor, but did not get beyond its first reading. The bill is a mild form of the New Zealand Act, and though not far-reaching enough in its scope, would have been a step to successful legislation.

In concluding my remarks on this important subject, I would suggest that our Association make known to the public its views on the matter, as we are considered to be among the best parties to propose a means of settlement; in so far, at all events, as the building trades disputes are concerned; which bodies, I may say, comprise about one-third the membership of the local Unions. The public recognizes that no industrial disputes are so detrimental to trade and commerce, as a whole, as those occurring in the building trades, and we as a body, being brought into such close touch with those trades, can properly advocate some means by which disputes of this character can be avoided or adjusted.

After careful consideration my own opinion favors the adoption of some such Act as that in force in New Zealand, adapted to our conditions, especially as that Act is creating an atmosphere of confidence and trust between the workers and their employers that possibly cannot be found to exist in any other country.

I take it that the system in vogue in Britain cannot be adopted here with success, as members of a Union cannot act independently of the Union; and from the circumstances also, that reference has frequently to be made by the local Unions to higher governing bodies, some of which are in foreign countries—possibly because our workers are more transient than in the old land.

The control of Labor Unions from a neighboring republic (however little or much it may be), especially in the interference of labor bosses and walking delegates, is to be deplored, as it completely blocks the way to the use of independent means of conciliation; creating a spirit of unrest and suspicion amongst workers, and antagonizing the employers at every turn, thus frustrating possible good relations between the disputants that would lead to harmony.

I would particularly refer to the position of the so-called third party in this question—that is the general public. That certain questions of vital importance to the public, for instance where food, fuel, communication and transportation are concerned, should be left in the hands of an organization over which there is no control, is not to be tolerated, but ought to be safeguarded; and however far any future Act may fall short in its power to settle any particular trade dispute, it should give no uncertain sound when such momentous questions are at issue. The Ontario Bill of 1903 proposed to deal with this aspect, but, as I have said, that bill is not yet law.

The great demand for both commercial and residential buildings, consequent upon the prevailing good times, has given us an opportunity to show in a practical manner where we in Canada stand in the realm of modern architectural practice.

Several important buildings have been erected in our larger cities, and they show careful study both in plan and general design; in fact, for the amount of money expended they cannot be surpassed on this continent. I have been repeatedly told by both British and American travellers, whom I personally knew to be capable of judging, that they were surprised to see such results in design and construction for the sums expended.

With regard to our residential work, I consider, too, Canadians stand in the front rank. Our architects have so studied both the convenient and artistic in ordinary house planning that even our mother country may pause to consider.

But there is one point we should guard against, that is the tendency of nearly all our work to be Americanized. Personally it is the only thing I deplore in our Canadian art; whether it is really having too much to do, or whether it is indifference (it certainly is not lack of ability), but the bulk of our work borders on plagiarism.

"I appreciate the fact that our needs commercially and socially are much on a par with our neighbors, but there are factors in our national and private life and our institutions that demand our impress. Why we should design and plan certain classes of buildings on the same lines as a foreign nation I cannot see.

I do not so much object to Carnegie money for our free libraries, but I do most strongly object to that money being clothed in American art on Canadian soil. The younger men in our profession are doing good work; some markedly so; and it is to such we particularly address this word of warning.

Every endeavor should be made in art schools and architectural classes to foster unconscious individuality that will master for itself our everyday problems, and clothe our needs in our own designing, in our own materials, and with our own tools, that all we do may bear our very own impress.

I feel that the past year has developed an excellent spirit among the members of our profession, no doubt greatly due to the social intercourse we enjoy through the local chapter. That this will lead us to uniting ourselves in the greater interests of our profession is devoutly to be hoped for.

Well we know we have a great country and a great people, and we, whose prerogative it is to hand down to posterity our nation's thoughts and aims "in imperishable stone" can more faithfully do so by unitedly aiming for greater results in our educational work and our social intercourse.

"Gentlemen, I thank you for the honor you have conferred upon me in electing me your president for the past year. The members of the Council have been most unselfish in their attendance to the duties devolving upon them, and have given unstintedly of time and thought to the Association's welfare.

Mr. Denon oresented and read the Treasurer's report as follows:—

TREASURER'S STATEMENT, JANUARY, 1904.

RECEIPTS.

Fees	$335.00	
Rent for Rooms	67.50	
Advertisements in Proceedings	703.74	
Interest accrued 1903	26.60	
		$1,132.84
Bank balance from 1902		1,001.08
		$2,133.92

EXPENDITURE.

W. R. Gregg, Registrar	$100.00	
Registrar's petty cash	25.00	
Rent	112.50	
Convention expenses	171.06	
Engrossing minutes	3.75	
Office supplies	30.50	
Printing	7.00	
Journals	24.05	
Books for library	37.65	
Gas account	8.85	
Insurance	5.53	
Engineers (common expense)	40.88	
Window shades for hall	6.00	
Membership Canadian League for Civic Improvement	4.00	
Membership American League for Civic Improvement	2.00	
Printing Proceedings	229.50	
Reporting Proceedings	58.60	
Postage on Proceedings	30.55	
Commission on advertisements, 1902	19549	
Commission on advertisements, 1903	206.75	
Educational work	38.20	
Examination expenses	15.00	
Solicitor's fees	25.00	
Discount on cheques	.45	
		$1,378.31
Cash balance		755.61
		$2,133.92

Mr. Denison: There are two items here of money paid to an agent for obtaining advertisements to be published in our report of the Proceedings for the year, and while they decrease the balance of the amount, we have been paid for two years during this year; I think about $800 will come to us for the advertisements that will appear this year, so that the report will be much better than it appears now. We paid out for last year $191.41, and for this year $206.75, both happening this year.

Mr. Denison moved seconded by Mr. Wickson, that the report of the Treasurer be adopted. Mr. Denison stated that the report had been audited and signed by the auditors.

Mr. Sidall: I have just one remark to make. I notice the amount of money spent this year for education amounts to only $38; I think the bare mention of that amount is enough to emphasize the point which I want to make. I think it is a very small sum to spend on the important work of architectural education.

Mr. Denison: I would like to say to my friend in reply that possibly he has not thought of the large amount of money we are expending on meetings, such as we are holding to-day and have held in the past, all of which is part of our educational system. We are having papers from eminent men, and these go into the hands of our architectural students. It is not such a small total as it would appear on the face of it. We have expended a great deal of money in publishing our Proceedings; the printing of them last year cost $229.50, a large proportion of which is for these valuable papers, which we look upon as a most efficient means of educating our students.

The President: I dare say we will hear something from the educational committee on this subject. If there is no further discussion I will declare the report adopted.

The President: I see Mr. Kivas Tully, our veteran representative, in the room, and I take much pleasure in inviting him to a seat on the platform.

Mr. Tully took a seat on the platform. (Applause.)

The Registrar's report was presented and read by Mr. W. R. Gregg.

REGISTRAR'S REPORT.

Membership. —The present membership of the Association is: Honorary members, 4; Toronto members, 34; members in other places, 34. Total, 72; one member more than in January, 1903.

A new rank was created by the Council in January, 1903, viz., that of Honorary Past President, and there were elected to this rank: Messrs. Kivas Tully, Henry Langley, James Smith and Joseph Connolly.

Meetings of Council. —The Council has met seven times during the year, with an average attendance of 6 members. These have all been Toronto members.

Students. —Five students have filed Articles in 1903, of which three are students in offices of

Toronto members, and two in offices of members in other places.

Five students presented themselves for examination in April, and of these four passed the first examination, one was allowed a supplemental in one subject of first examination and one passed the second examination.

Proceedings. —One thousand copies of the Proceedings were printed and distributed. A permanent mailing list has been carefully prepared in such a way that it can be revised and added to from year to year, and the volumes are mailed or delivered mostly by single copies to Societies and persons interested in architecture at home and abroad.

A number of valuable and interesting exchanges are received from other Societies in return.

Civic Improvement. —This Association in 1902 became a member of the American League for Civic Improvement, which was formed in 1900 in Springfield, O., and has held annual conventions in Buffalo, N. Y., St. Paul, Minn., and Chautauqua, N. Y., and will meet in 1904 in St. Louis.

The Ontario Association of Architects was represented by W. R. Gregg at the Chautauqua convention in 1903.

Three members of the Ontario Association of Architects assisted in the formation of the Canadian League for Civic Improvement in Toronto in February, 1903, and the Association has also become a member of this League.

Guild Bequest. —A Trust Deed has been prepared by Mr. W. D. Gwynne, the Solicitor of the Association, and signed and sealed, by which a sum of over $300 is placed in trust by the surviving members of the former Architectural Guild of Toronto, to be invested until the fund and accumulations shall amount to $400, after which the income is intended to be offered as a prize to students, this prize to be known as the Architectural Guild Prize.

A full copy of this deed will be published in the Proceedings for 1904.

Committees to Report. —Toronto Chapter, Mr. E. Burke; Month'y Meetings, Mr. E. Burke; Library and Rooms, Mr. A. H. Gregg; Editing, Prof. C. H. C. Wright; Publishing, Mr. John Gemmell; Municipal Building Laws, Mr. A. F. Wickson; Legislation, Mr. J. A. Pearson; Membership, Mr. A. R. Denison; R. I. B. A. Examinations, Prof. C. H. C. Wright; Joint Association and Eighteen Club, Mr. A. H. Gregg; Educational Committee, Mr. A. H. Gregg.

The President: I think instead of presenting the report now, and discussing it, in order to save time, we will take up the reports of the several sub-committees. The first is that of the Toronto Chapter.

Mr. H. E. Moore, secretary, reported on behalf of the Toronto Chapter, Mr. Edmund Burke for the Monthly Meetings Committee; Mr. A. H. Gregg for the Library and Rooms Committee, Mr. Helliwell for the Editing Committee, and Mr. Gemmell for the Publication Committee. These reports were adopted.

REPORT OF THE MUNICIPAL BUILDING COMMITTEE.

Mr. Wickson presented the report of the Municipal Building Committee as follows:—

I do not know that I have anything to report. Although my draft by-laws were sent in there last January nothing has been definitely, that is, finally, done yet. I wrote to the Board of Control once or twice since Mr. Fleming was appointed, and I have also seen him. He told me just prior to the appointment of the City Architect that one of the first things he would do would be to take up this work. I am given to understand that Mr. MacCallum is devoting his time to that now, and I suppose before long we will come to a final discussion on them.

The President: We have been waiting for that since we were young in the profession—most of us.

REPORT OF THE LEGISLATION COMMITTEE.

Mr. Gouinlock: The chairman of the committee is not present to-day, but I might say that the Association did not deem it advisable to urge for further legislation this season, and they decided to leave the matter in abeyance for the present.

REPORT OF THE MEMBERSHIP COMMITTEE.

Mr. Denison presented the following report:—

I have nothing of special interest to report. Matters are just about in the same position as they were this time last year; but while I am on my feet I might say I was one of the representatives to the Technical School Board, Mr. Gray being the other. A new Board of Education has recently been elected and the old Board goes out of existence. Mr. Gray and I attended the meetings on many occasions and did what little work we could. I only hope the new system may be all right in its working, but so far as the Technical School Board is concerned I have my doubt.

Mr. W. R. Gregg: I would like to supplement Mr. Denison's remarks. He has really reported for two committees, the Membership Committee and the Technical School Board. With regard to the question of membership the Council slightly amended the by-law a year ago, giving them discretionary powers to admit architects who had not passed the regular examinations, if satisfied as to their general fitness and qualifications. We received one member under the amendment to the by-law. It still remains in the book, and it may be advisable to cast around the province and see if there are not other professional men who should be members of the Association.

Mr. Denison: I think that ought to be put prominently in our Proceedings this year, so that it will be noticeable.

The President: In the absence of Professor Wright, the chairman of the R. I. B. A., is there any person to report?

Mr. W. R. Gregg: The Registrar's report gave the number of students examined, and that is practically all. Mr. Taylor, the Secretary for Canada, writes, enclosing notice of the R. I. B. A. examination to be held.

MONTREAL January 4th, 1904

The Secretary Ontario Association Architects :

My Dear Sir:—I enclose notice of the next R. I. B. A. Examinations, to be held in June, and on behalf of the R. I. B. A., may I ask that you will kindly bring this before your Council as soon as possible, and that they will be good enough to give instructions, that all the members of the Association may be notified by circular of this Examination, for their own information and others.

The R. I. B. A. will greatly appreciate the cooperation of our Architectural Associations, in making these Examinations as widely known as possible.

I remain,

Very truly yours.

ANDREW T. TAYLOR.

Hon. Secy. for Canada, R. I. B. A.

The President: Possibly Professor Nobbs can give some information on this subject.

Prof. Nobbs: Mr. Taylor has taken up the points in his letter. Mr. Taylor told me himself that he is leaving Montreal in the spring, and the question of getting some one to take up the work is sure to arise. I thought Mr. Taylor would probably mention that in his letter to you. I am not a member, but my own feeling is it would be very desirable if your Association could see fit to take up the work of the Secretary of the R. I. B. A. examination, because I think you will have more R. I. B. A. students from Toronto than you are likely to get from Montreal. Another point is the feeling of the R. I. B. A., that if these examinations were held in South Africa and Australia, as well as in Canada, it should hold primary and intermediate examinations in addition to finals. That, of course, is a matter of arrangement for the R. I. B. A.

REPORT OF THE JOINT COMMITTEE OF THE ASSOCIATION AND THE EIGHTEEN CLUB.

Mr. A. H. Gregg made the following informal report:

On Oct. 30th, 1903, it was decided to form a Joint Committee, representing the Association of Architects and the Architectural Eighteen Club. Formerly classes had been held by both of these Associations for the students, and it was thought that by amalgamating much better work could be done. The Joint Committee is composed of three members of the O. A. Association and three members of the Eighteen Club. A mathematical class is held in our rooms here under the tuition of Mr. A. H. Harkness, B. A., who was formerly one of the instructors of the School of Science, and classes in design are held at the Central School of Art and Design. The mathematical classes were left to the management of the O. A. A. members of the committee, and the classes in design to the members representing the Eighteen Club. These classes a year ago were not well attended, but I think it is a proof that we are on the right lines, that the attendance is more than doubled this year. Last year the students in the mathematical class numbered seven, and I think the average attendance was much less than that. I have not a memorandum of the attendance at the classes in design, but I think it was very small, too. This year we have fourteen members in the mathematical classes, just double the number; and from all accounts the students display great enthusiasm in the work; and we have found it necessary to divide it into two sections, junior and senior. In regard to what Mr. Sidall has said about the amount of money paid out for educational purposes, our mathematical instructor receives a salary, but at the time of the last report very little had been entered in the Treasurer's report. Still, one of the main contentions of the committee was that we should have a professional man in charge of this class, and pay him properly for his services, and I think the result has proved our contention a just one. Mr. Harkness has taken a great interest in the class, and has been the means of arousing a great deal of enthusiasm, and I think the result will be a large attendance at our examination this year, and in a few years these younger members of the profession will be becoming members of our Association, and having gone through our regular course, should prove a most valuable addition to our Association.

The President: We have heard the report of the Toronto Chapter, the Municipal Building By-law Committee, the Library and Rooms Committee, the Legislation Committee, the Membership Committee, the Registration Committee and the report of the Educational Committee. I would like to have an acceptance of these reports moved and seconded, and we will discuss their adoption.

Mr. Gouinlock: I have much pleasure in moving the adoption of the reports as presented.

Mr. Burke: I have much pleasure in seconding that motion. Carried.

NEW BUSINESS.

The President: Under this heading I would like the Registrar to read a letter received from one of our out of town members.

The Registrar: This letter is from a member in Ottawa, Mr. Alexander, of the Department of Marine and Fisheries; he was one of our charter members.

Ottawa, Dec. 6, 1903.

To W. R. Gregg, Esq.,
Registrar O. A. A.

Dear Sir,—In regard to the convention I would feel much pleasure in being there, as my interest in the aims and objects of the Association has never lessened since our organization began; and if all has not been attained which we have sought I would regard that as the reason for more determined future effort. In this connection I specially deplore the cessation of active steps to legalize the title of "Architect," as I regard it as vital to the future success of the Association, as giving the Association the necessary control over its members in all professional questions of a practical, and ethical character; without which it seems to me impossible to bind men together in mutual sympathy.

Again, I know of Architects who have dropped their membership in the Association because of its being run so much as a Toronto institution. This objection I hardly sympathize with, but rather feel grateful to the Toronto members who have so unselfishly devoted valuable time to the Association; but I regard it as a fair question whether the utility of the Association would not be furthered by the annual convention being held in different large business centres yearly.

With every good wish for the Association, I am, dear sir, Yours very truly,

Fred. J. Alexander.

The President: This letter of Mr. Alexander's touches on two points—legislation and the question of the advisability of holding our annual meetings in different cities over the province. In regard to the question of legislation I do not think it is desirable to bring it up, as it is in the hands of a special committee, and we have their report, but as you think about that; however, I think it would be well to discuss at this meeting the advisability of holding our conventions east or west of Toronto; and I think in deference to our outside membership we should make a pronouncement, and seriously consider it, so as to be in a position to answer letters fairly written as this has been.

Mr. Gouinlock: In speaking of this proposition or scheme, to hold annual meetings some other place than Toronto, it seems to me there are so few architects in the various places in Ontario we couldn't undertake to carry it out successfully. We have discussed this before, and no city would undertake to carry it through. Unless the proposition was from the architects of Ottawa, or Hamilton, or some such place, I do not see that we are in a position to move in this matter.

Mr. Munro: I am sure I would be pleased to see a move made in that direction; for myself, I think we meet here in Toronto, in the Association's rooms, probably to a greater advantage than any place else; but what I think might be done is a midsummer convention, or something of that kind, to be held in different outside towns. In Hamilton there are probably fourteen or fifteen men practising architecture, and some of them were formerly members. I do not know that I can say anything further. I would like to see a convention in midsummer in Hamilton.

Mr. Simpson: What strikes me is this. If it is so difficult for this gentleman to leave Ottawa how much more would be it be for the number from Toronto to go to Ottawa. I very much like the suggestion of an excursion to some of these outside places in the summer. However, I think that it ought to be on the invitation of the architects of the city we visit.

Mr. W. R. Gregg: Would it not be well in replying to Mr. Alexander's letter to suggest that he inaugurate a movement in that direction among the Ottawa architects, and some sort of excursion, if not the annual convention, might be made to Ottawa. There is a great deal of interest there to architects, and it may be the means of more architects there joining the Association.

Mr. Sidall: I agree with what has been said by the members who have already spoken on this question. We have discussed it before; I think that on the first day of our proceedings last year the very same sentiments were expressed, and I believe we all agreed that it would be a nice thing and a very helpful thing. The trouble is it would be very difficult for so many to leave Toronto to meet so few in another city. However, I feel that something along this line could be arranged for, and I will move that that letter be handed over to the Legislation Committee with that object in view.

The President: Might I suggest the Membership Committee?

Mr. Baker: I have very much pleasure in seconding that motion. I think I had the pleasure of bringing that subject up last year for discussion. I see that the membership of Ottawa and Kingston, combined, is 7, and that of Hamilton and London, combined, is 6; it means to me that London and Kingston are the only two places where the convention could be held to be central, Kingston taking in Ottawa and Peterboro and towns in that part of the Province, and London taking in the towns in their part of the Province. I think something must be done if we are going to increase our membership. I think there are more than 70 practising architects in Ontario, and that there are nearly that number in Toronto. I think nothing further can be done than refer it to the Committee.

Mr. Simpson: Might it not be well to suggest in replying to the letter that the Association would be glad to consider the question of forming an Association Chapter, on the occasion of such a visit.

The President: I might say that the annual convention of the Quebec Association of Architects, at first held only in Montreal, is now held, alternately, in the cities of Montreal and Quebec. When down there I inquired as to the result, and they said it had been a wonderful success. Meeting in these two large centres has been conducive to a great increase in their membership, and in the general tone of the profession in that Province. The membership of the Ontario Association of Architects shows that we have a local membership of 34, and a non-resident membership of 34; and it seems to me now that we ought to pay some attention to this matter, possibly it can be best done through the committee that Messrs. Sidall and Baker suggest, and I will therefore put to you the resolution of Mr. Sidall, that this letter and correspondence be referred to the Membership Committee, and that they reply to the writer, having heard the sentiments of the Association.

Mr. Sidall: I still have the matter of the education of our students in my mind, and I think that some efforts should be made. Our own education has perhaps gone beyond the rudiments, but for the sake of coming architects I think we should do something more than we are doing now. I think we are on the right lines; the prize that has been offered, or is about to be offered to students of a travelling scholarship, or some other incentive to study, is a move in the right direction; but I think that during the coming year some further effort should be made. It seems to me we have money in hand which might be used for that purpose, and I would like, if the architects present agree to the sentiment, that it be taken up more enthusiastically than at the present time.

The President: It is vital to our Association and I would like to hear a full discussion on this subject.

Mr. Denison: I was out of the room, unfortunately, at the time Mr. Sidall made his remarks, but it occurs to me, and it has always seemed to me to be strange that the architects should be expected to pay for the education of their students. I think it is the duty of the Government. In every other profession and every other calling in life the Government makes provision for education; and we have received probably the least support of any body of men in Canada to-day. There is nothing, surely, so important as architecture in the building up of a new country. There is nothing that shows what any country is capable of to the extent that architecture does. But the Government seems to think that anything is good enough as an architect, and they do nothing for us.

Mr. Sidall: There is an old saying that if you want a thing done you should do it yourself.

Mr. Denison: It looks like it.

Mr. Baker: We might hear something about the President's scheme for scholarships; at the beginning of the term I understand that was all cut and dried, but in his report we hear nothing about it.

The Registrar: I would like to draw attention to the fact that the first step has been taken in the matter of scholarships or prizes. That is to say, the Toronto Architectural Guild Fund has been put into shape. The fund was originally $400, but through the loss in the Farmers' Loan Company it is now between $300 and $350, and it has there got to remain until the interest or the liberality of some friend brings it up to $400. When this fund amounts to $400 the interest goes for the first prize ever offered by the Ontario Association of Architects; it may be a prize in books, or a medal, I don't know just what it will be, but if we ourselves contribute a small sum and bring it up to $400, it means there will be a prize.

Mr. Gemmell: Is there anything to prevent the Association bringing it up to $400 without waiting for the interest?

The President: No.

Mr. Gemmell: If I might be allowed I would move that a portion of the Association's funds be used for that purpose.

Mr. Sidall: I second that motion.

Mr. W. R. Gregg: I do not feel quite so despondent as Mr. Sidall does about the educational work of our Association. We have very good classes now, and we have taken a great deal of trouble to prepare suitable examination papers to test the ability of the students, and I believe this year we shall have students coming all the way from Winnipeg and Port Arthur for examination. As the interest grows we may expect more, and all that is necessary is for each individual architect to encourage students to take advantage of these classes.

Mr. Burke: The hour has now arrived for another session, and a large number of visitors are here. Would it not be well to adjourn this discussion and put it in some time to-morrow morning?

The President: I think that is quite in order. You must remember that Messrs. Baker's and Sidall's motion is before us, namely, "That the fund known as the Architects' Guild money be increased to $400." We have with us this afternoon Professor Carpenter of Cornell University, Ithaca, whose name is a household word to us in Canada. The professor may not be aware of that, but if he knew how we, as practical architects, value his works, which are in our Library here, I think he would feel that his life work had not been in vain. Without further preliminaries I will introduce to you Professor Carpenter of Cornell University. (Applause.) I want you particularly to take note of Professor Carpenter's lecture, as Mr. Wright, who was to have led the discussion, is ill, and we shall have to depend for the discussion on the various members and friends present.

At the evening session, at which many persons outside the profession were present by invitation, Mr. Challoner presented a paper on "Mural Decoration," an abstract of which will be printed in a future number.

At the close of Mr. Challoner's address, Mr. Gouinlock said: I am sure we have all listened with a great deal of pleasure to the very able and instructive paper on mural decoration given to us by Mr. Challoner, and I have a great deal of pleasure in moving that he be tendered a hearty vote of thanks.

Mr. P. W. Ellis: I have much pleasure in seconding the motion.

The motion was put and carried unanimously and tendered by the President to Mr. Challoner.

SECOND DAY.

MORNING SESSION.

Wednesday, 13th January, 1904, 11 o'clock a.m., the President, Mr. Symons, took the chair and called the meeting to order.

The President: There were two items of unfinished business yesterday that I should like to dispose of this morning. One of these is particularly interesting to outside members, who are perhaps better represented to-day than they were yesterday; but there is still room for better representation. The motion was made by Mr. Gemmell, seconded by Mr. Siddall.

Mr. Siddall: Mr. Gemmell, who moved the resolution that I had the pleasure of seconding, is absent. As far as I understand the motion, it was that a sufficient amount should be contributed to make up the necessary fund to pay the scholarships for which there is part in the funds coming from the old Guild. That is the gist of the motion, although it may not be in identical terms.

The President: In regard to that question, it may not be out of place to make a few remarks. The Guild money, as most of you are aware, was not handed over to us until recently. The conditions have been agreed to and a document has been drawn up giving the Association control of these moneys; one of the conditions is that it shall not be used until it reaches the sum of $400. The sum is about $320, and this motion is that we increase this sum to $400 to make it available for the use of the students at once. The idea is that the interest derivable from this shall be competed for annually by the students of the Architectural Association, and the award be made in accordance with the wishes of the Council, such as a medal, or a ticket of leave or it may take such a shape as is thought best. I would like to hear it well discussed, because it will depend on what you do this morning whether it can be used for many years to come, probably six or seven.

Mr. Belcher: How do you hope to accumulate $400, even depending on the interest?

The President: We have $320, which will probably now be raised to $360, by another dividend which I understand will be paid by the Farmers' Loan Company, in which institution it was unfortunately placed. It seems to me that we have no way of increasing this to the limit, $400, unless from the funds of the Association or by compounding the interest. We are anxious to have this operative. There is nothing like a scholarship even if it is only the sum that we can command now. It is in order to give a little snap to our educational work, that the Educational Committee, who are really at the bottom of this proposition, wish you to consent to this this morning.

Mr. Baker: I am heartily in accord with the motion, and will support it strongly; but it strikes me it does not go far enough. I would like to see a little more done if we can. In the past I think we have erred in doing these things in too small a way. I will throw out a suggestion that it be raised to a sum that will produce at least $25 a year. I should think that might be arranged in some stock which pays an interest of six per cent., some solid company, an insurance company or something of that sort. That sum we might raise. I do not know how it would be controlled by the deed of transfer, but I hope the meeting will see fit to go a little further than providing a few dollars to make up the $400 which we have received in such a generous way from the Guild.

W. R. Gregg: This money that is given to us by the Toronto Guild was voted in the lifetime of the Toronto Guild; it has been arranged that the prize is always to be known as the Toronto Architectural Guild School prize. This does not prevent any number of other prizes being raised in the future; there might be a five thousand dollar investment made for another prize. The Council has a perfect right to change the prize from one thing to another; it may be books or it may be a medal; the trouble with the medal is that it would take a good deal of money to buy the die and we would have to keep the young men waiting a few years.

Mr. Simpson: They would die in the meantime.

Mr. Gregg: The credit has to go to the Toronto Guild. The money was $400, and it should have been $500 or $600, if the interest had been at six per cent., as Mr. Baker says. But it has to be invested at a low rate of interest, because it is trust money, and we have no more right to put it in stock than we would have to put any other trust money. It has to be the safest kind of an investment according to the agreement. I think it would be possible to make it up to $500, but the credit goes to the Guild. It should be kept in view that the old Guild gets the credit of the whole thing and if we add $150 we must give the credit to the Guild. The prize may be changed from a prize to a medal, but it always remains as the Guild prize or the Guild medal.

The President: Mr. Gemmell (who has just entered the room), we are speaking of your motion of yesterday to increase the Guild money.

Mr. Gemmell: I gathered from the few words our treasurer spoke of making it $500 and presenting it. I thought if the interest were put in, making it up to $400, it would be such a trifling thing for the Association to do and it would make the fund immediately available. Then there would be reason in calling it the old Guild fund, because it would be only a matter of $30 or $35 of other funds in the $400. I think I will stick to my original motion to

make it $400, so as to make the prize immediately available.

The President: Do you wish to make an amendment, Mr. Gregg?

Mr. Gregg: No. I was answering Mr. Baker. It is the Guild fund, a thing by itself.

Mr. Baker: No matter where it came from, it would be from the Association. It would be handed out by the Association like all scholarships.

The President: It is to be handed out by the Association, but it is to be known as the Guild Scholarship.

Mr. Gemmell: I think that $400 is quite an amount to grant, suppose it is to be donated for one special purpose. The Association has plenty of ways to spend their money and I think this particular Guild fund should be limited to $400 net.

Mr. Siddall: There is a way out of the difficulty, perhaps. It may be wise for the Association each year to make a grant and double the amount that the interest on $400 would produce which would only be about $20. If the Association were to make a grant of a like sum each year it would make a prize worth having. I think that if the amount is made up to $400 this year by the Association, it would be a prize worth having next year; and then the next year we would double that prize by granting the sum of $20 from the funds of the Association as an additional impetus to the students. I think it would be wise to go slow in the matter. This is a fund by itself; and it we wish to get another fund we can do so. As far as this particular fund is concerned, I think it would be wise to deal with it separately.

Mr. Simpson: I think the Ontario Association of Architects ought to have some idea what they are going to put this money to before they bind themselves down to any amount. I do not see what good $16 a year is going to do any student. We must have some idea what good can be done and then let us pass a resolution sufficient to cover the purpose we intend to put it to.

Mr. Gemmell: This fund is a thing beyond our control; it is established by this document which Mr. Gregg accepted yesterday, and must be used for that purpose, or the interest on it.

Mr. Baker: After this resolution is carried we may want to make the interest up to the sum of $25 out of the funds of the Association; that will only take a few dollars out of funds to make up the difference between $16 and $25. After this motion is carried, I will make a motion to that effect.

The President put the motion that the Guild fund, which amounts to something about the sum of $320, be increased to the sum of $400 by the addition of such necessary sum from the exchequer of the Ontario Architects' Association. Carried.

Mr. Baker: I would move that a sum be paid or set aside by the Association sufficient to bring the interest accruing from the Guild fund up to $25 each year.

Mr. Belcher: I have much pleasure in seconding that. It is a good plan.

The President: It is very pleasing to hear that seconded by an outsider; we are very anxious to have the support of our outside men. Carried.

The President: I think it would be well while we have so many outside men here to discuss the subject of holding our meetings in some other cities than Toronto, or, as was suggested, of holding a summer convention. We should like to hear a discussion on that subject this morning.

Mr. Baker: To bring the matter before the meeting I would move that the Council be asked to consider the advisability of holding a summer meeting in Kingston at a convenient time.

Mr. W. R. Gregg: This matter was disposed of in a way. The letter suggesting these meetings was handed over to the Membership Committee, which would report to the Council.

The President: We have quite a few outside members here this morning, and I would like to hear what they think of such a proposition.

Mr. Bell: Although I am a native of Toronto, I reside in Ottawa at present, and I know that there is a hard feeling in connection with the matter. I think the only way to overcome this difficulty and keep up the Association, as we would like to see it kept up, would be either to hold the winter meetings occasionally in the outside cities or have a summer convention, and probably the summer convention would be the better. It seems to me that about three places would do, London, Hamilton and Ottawa; Kingston, of course, is an older place, but it is such a small town that it does not class with Ottawa. My opinion of the matter is that something must be done, and I think the summer convention would be better. Probably that matter could be best discussed if left entirely to the Council and that is what I would suggest.

Mr. Belcher: I agree with this proposition; I am too conservative to upset the old Association by travelling about particularly in the winter. I think Toronto is a more convenient place to nearly every one, as far as Ontario is concerned. I think at the same time it might be well to have a summer convention, and especially for the students. And in consideration of the students I think it would be a nice thing it it could be arranged.

Mr. Bell: I belong to the American Society of Civil Engineers, and also to the Canadian Society of Civil Engineers. The American Society holds its convention during the summer and I have attended a great many of them during the last twenty-five years; I have found these meetings very useful for the purpose of bringing the members together and getting them acquainted, socially, especially. I think there is a feeling of something of that kind in connection with our Association, and something ought to be done.

Mr. Burke: I think, as far as the annual meeting is concerned, it would be enough almost to wreck a particular meeting to have it outside of Toronto; the majority of the Council live in Toronto and we have all the machinery here for our meetings. We have our rooms and our place for exhibition, and having had it for so long it seems it has got into a certain groove, and to take the annual meeting out of Toronto would be very serious. I think if we could manage a summer convention and have an interesting as well as a social meeting, it might be a good thing for the Association.

The President: I think we can safely leave this in the hands of the Council, especially after hearing from so many of the outside members. We have with us to-day Professor Nobbs, of McGill University, Montreal. He is to give us a paper on the subject of Delineation of Architecture.

Professor Nobbs was greeted with applause.

AFTERNOON SESSION.

When the convention reassembled, an address was delivered by Prof. Mavor, of Toronto University, on "Recent Developments in the Planning and Improvement of Cities in Europe nd America," and was followed by a paper by Mr. F. G. Todd on "The Advantages of a Park System."

The election to Council resulted as follows: Mr. W. R. Gregg, Toronto; John E. Belcher, Ottawa; and S. G. Curry, Toronto.

"THE DELINEATION OF ARCHITECTURE."*

By Prof. Percy E. Nobbs.

Mr. Chairman and Gentlemen:—Although I have always held that the practice of opening a paper with an exercise in apologetics brings those who employ this artifice for breaking the ice peculiarly under the ban of the old adage "Qui s'excuse s'accuse" I am constrained to take this occasion to apologize once for all to the Profession in Canada, to my future students and to any of the outside public who may find themselves obliged out of politeness to give me a hearing, for the assumption of a University Chair by one so wholly lacking in dialectic and oratorical skill as I. A ray of consolation comes to me however on reflecting how rarely the natural and artistic instincts are combined in one individual and it is to the latter that I pretend. The best of our profession in England at least are silent folk; in this I find comfort on such occasions as the present.

From this circumstance I would almost argue that architectural matters are not fit subject for conversation. I doubt if by spoken words any piece of work has been satisfactorily described by one man to another who had not seen the thing. No written description has ever conveyed the remotest resemblance of an architectural idea to me and I rejoice that when you did me the great honour of inviting me here we were able to select a subject which would not call for an effort at describing what must be seen to be felt, and this brings me to my first point, which is that a good drawing of an architectural subject is more eloquent of the beauties that be in wrought stone than all the poets and orators, and our business just now is to enquire that constitutes excellence in an architectural drawing—a question by the way of no possible interest to the lay mind.

It is almost unnecessary to remind a professional audience that architectural draughtsmanship is a new thing. So recently in the history of our art as the building of the Parthenon in 438 B.C. a set of contract drawings was a thing unknown, far less a set of client drawings and a perspective—the Gothic men drew badly, and when they did not just go ahead and build they used models by way of preliminary studies. The renaissance architects made moderately good drawings of old Roman remains but did not rely greatly on drawing for proposed works. Models were found far more satisfactory than drawings and it is only the cost that prevents their more frequent use to-day.

In the separation of the functions of the builder and the architect we have the real reason for designing by the indirect paper process to the extent we do; and this being a condition past remedy we do well to accept it and consider the draughtsman and his work.

Nothing has contributed more to the development of draughtsmanship than the recent revivals which have taken place of by-gone styles which have led to the study of old work by means of measured drawings--the only way old work can be studied. A secondary motive for good drawing may be found in the system of selecting an architect by competition which rages in England greatly I think to the detriment of our art and the debasement of the profession, but that is a matter beyond the scope of these notes. Sufficient but to point out how much competitions do to stimulate the skillful delineation of architecture if not the art itself.

We have then three main classes of architectural drawings: (a) Working drawings necessitated by our professional conditions and the unskilled and inartistic state of the labour market. (b) Competition and clients' drawings no less intimately connected with our professional systems than the working drawing and (c) Measured drawings and sketches which are pre-eminently works of study.

Owing to the way in which picture painting has monopolized the title of art even some architects have false ideas as to what a drawing should be. There are two ways of drawing a thing. From the painter's point of view it is not the thing that is beautiful but the appearance of it, as Mr. Ruskin and others have pointed out. Moreover his drawing of it is meant to be an end in itself, a thing imbued with some kind of beauty, and it is unnecessary here to analyze the many elements of beauty in painting. How different is the draughtsman's purpose! Who outside the profession cares for the finest elevation that ever was draughted? In the matter of labour and even in technique it may rival any painter's work but when the competition is lost or the building completed it has served its turn and to do this it is essential that attention be not wasted on an aspect of the building but upon the facts of the case. An architect may imagine his building in pale pink frosty sunshine or midday glare or silhouetted against an evening sky but as far as drawing the thing goes it is of no use to him or anyone else to represent it otherwise than as it is—so many masses related by proportions, contrasts, textures, colors. The style of drawing which most easily attains the object of representing a thing AS IT IS as opposed to as it may happen to appear is the best. Having thus made clear the object of the draughtsman, let us consider his materials and technique.

This we can do in a word. India Ink is, and I think will always be, the chief medium for the expression of architectural ideas. Fads for pencil, wash, or brown ink come and go but the preeminence of the great hexagon stick bound up in string is never seriously challenged. In the use of ink a great change has come about in late years. The thin fine line of the last generation has become a lost art, which is a pity, but not wholly to be deplored, for with it has gone the horrid practice of back lining by way of showing the shaded side of things. To-day the English architects draw with a stout line—often far too stout—sometimes a silly affectation, and the reason is a practical one as we all know. Tracers' eyes are not to be ruthlessly sacrificed. If the ink goes on strong and juicy one can get a sunprint through "Medium Whatman" while if reduced photo lithographs of our drawings are to grace the sympathetic professional papers what time we are "branded with the infamy of a second premium" as a sporting competition architect has styled it, then a thick clean and unrubbered ink line will stand us in good stead. Of course thick line drawing to small scales leads to all kinds of impressionisms on the draughtsman's part,—so much has to be omitted—a single line in the right place must tell that a three membered architrave is here proposed, while sculpture can only be indicated by dots, also in the right place. To draw well with a thick line even ½-inch scale is very difficult, and the mannerisms of the skillful are often attempted by the would-be smart draughtsman with deplorable result. A rather wholesome reaction in favour of more refined methods is setting in but the thick line has come to stay and the student should learn from the outset to use it, for by

*Paper read at the annual convention of the Ontario Association of Architects, January, 1904.

long use only can he discover the marvellously sympathetic qualities of thick black ink and white paper.

Especially is this so when we consider the double motive with which the student bends over his board. His success on the lower rungs of the professional ladder depends entirely on his being able to be of use in the draughting room while the only way in which he can assimilate any idea of what architectural details, or for that matter, anything else Architectural is like, or how big things should be, is by drawing them as they are,—plan, elevation and section, even of an acanthus leaf. That is the only way I know of becoming heir to the least morsel of the glorious heritage of tradition in our art.

Mr. Kipling has told us that there are "More than thirty ways of constructing tribal lays and every—single—one of them is right." The analogy which exists among the arts here breaks down a little. There are many ways of rendering Architecture and a great many are wrong, but happily we need only deal here with some of the right ways.

The remainder of this paper will practically amount to a comparison between the methods of the students of the R. I. B. A. and the Ecole des Beaux Arts in Paris and I venture to hope the meeting will agree with me that the ideal lies between the two.

Before plunging into technical questions of rendering it is worth while pointing out that a fashion in drawing is very apt to lead to a fashion in designing. I will challenge any man who has worked in an architect's office to look at some of the new buildings in Glasgow and not feel his nostrils assailed by the delicate aroma of tracing paper and seem to hear the rip of the pencil up the T square and the rattle of the sets. The technique pervading these and many more designs of the Art Nouveau adherents is not the rational technique of stone or even steel. It is the technique of the draughtsman and his tools not of the builder. It is as if a sculptor modelling in wax for bronze had forgot the nature of bronze in his enthusiasm for his wax.

Coming now to questions of practical draughtsmanship, the due relation of accuracy and speed must be considered. Inaccuracy is as inexcusable in a draughtsman as sheep killing in a collie dog. In the training of draughtsmen it is absolutely fatal to develop the over painstaking kind of drawing which encourages slow, I would almost say lazy, habits. It is here that method in setting about one's work tells. Accuracy and speed are not inconsistent in drawing any more than in whist and it takes both qualities as we all know to make a man worth a salary. This is an important point in considering methods of rendering.

As the object of all our drawing is to present a building as truly as possible in accordance with limitations imposed by scale and medium—ink, soft pencil or wash—we find certain conditions amounting to conventions imposed upon us which it were inartistic not to recognize.

An outline drawing in ink (such as is demanded by the conditions of most competitions in England) must of necessity ignore all question of local colour and shades and shadows and yet if it fails to convey the idea of mass it is wholly futile. The heavy lining in of the boundary lines of nearer masses and the thin lining in of all jointing are tricks which in inexpert hands lead to strange results, but a marvellous amount may be expressed by this means concerning the mass, texture and scale of the work. A great mistake is often made by giving undue prominence to the jointing while the practice of jointing little bits here and there is well enough on a working drawing but very distracting on a draught which seeks to show a committee or a client what is proposed, as there are no outlines of parts on a building as seen, and if we adopt the convention of showing the forms of things by this convenient means the jointing which is subsidiary and does consist of lines should be rendered with a line of very different quality--thin, in pale ink, or pencil, as opposed to stout lines to show form. Some beautiful drawings of Neo Greek work appeared a couple of years ago in the "American Architect" in which these principles were observed.

In making two lines do the work of three and express the effect of a moulding, a good deal of insight is often required. The practice of breaking the inner lines of a moulding has much to recommend it as long as it does not become a mere habit or trick instead of a means of expressing the several groups or orders or separate pieces of which a moulding is made up. To line in the top and left side of all panel moulds and leave the bottom and right side open, is a convention to impart shadow too crude to be encouraged. It is little better than the old back lining to my mind.

In lining in the freehand work of caps or the enrichments of mouldings, good steady penmanship, without variation in thickness is to be aimed at, for a drawing in line once started must be homogeneous or the different parts in close proximity will appear nearer or further according to the amount of ink lavished upon them.

The fashion of drawing all freehand work in with a tremulous or loose line on the ground that hand work should contrast with mechanical work and that error in a shaky line is not so apparent as in a clean sweep, has, I think been followed too much. I do not recommend any one who has the faculty for drawing clean to a small scale, to draw shakily on purpose—it might easily demoralize the sense for refinement in the scale of detail.

I have here a sketch of Beverley Towers lined in with a laboriously shaky line. There is much charm about the drawing; the effect is quaint and the value of things stunningly well attained, but supposing a man can sketch in the direct way that Mr. Blomfield did for his book on the "Renaissance in England" he should not affect the studiously shaky line in ink over a careful pencil drawing.

As draughtsmanship is one of the lesser arts in which individual style has really no great scope, we find extremes of mannerism manifesting themselves instead. The self consciously loosehanded style is well exemplified in the drawing of the famous font in Siena. There is a little too much sleight of hand and not enough sympathy for the peculiar character of cincocento carving to be thoroughly commendable, but the fact is patent that Mr. Fulton is possessed of a rapid and business like way of putting down approximate facts. This is an example of extreme, not typical English drawing, and it is unnecessary to say that no academic draughtsman can see much virtue in it, but your academic draughtsman errs quite as much the other way. When mannerism in draughtsmanship of whatever kind gets the

length of obliterating instead of sympathetically enforcing the differences between various subjects rendered, it is time to remember that there is such a thing as approximate truth which is not entirely compatible with meretricious affectations either in speech or drawing.

The drawings submitted annually for the various travelling studentships of the R.I.B.A., afford us excellent examples of English methods and these sets of measured work from Melrose Abbey, Houghton in Norfork and Aston Hall, Birmingham, will give some

From a Photograph.

idea of faithful rendering and good workmanlike methods of execution without undue affectation of technique.

Before leaving this matter of scale drawings in ink line it may be well to call attention to a few of the tricks of the trade which enable us to express, albeit in a conventional way, something of the interest that is in caps and carvings, and sculpture. When sculptured decoration is shown it is impossible really to give it its value by uncompromising line drawing, while if patched shading is resorted to we at once knock the pure line drawing of the architecture out of time. The draughtsman's method should be to draw the folds of drapery &c., more thoroughly on what may be supposed the shaded side, leaving the strongly lit portions in unbroken white. Cast shadows should be very sparingly employed and only where the line drawing fails to convey an idea of what is meant.

As to the crossing of ink lines at corners much difference of opinion prevails. When exaggerated, the tangle of lines quite defeats the object, which is to make it clear what is an arris and what a bead or moulding on a small scale drawing with thick line. When systematically practiced and not overdone the crossing of lines makes for rapid work and clearer meaning. I have known cases, however, in which a laborious draughtsman has gone over a drawing, crossing all his ends to give it a smart look—such second hand affectation needs no comment here. The unskillful draughtsman is very apt to draw far too much detail on a small scale drawing. We have all seen elevations in which the caps of Corinthian columns appear as so many black blotches while a delicate swag is made to tell with more force than a three foot cornice. As the scale gets smaller so should the amount of detail sought to be represented.

Turning now to full size details, I would here commend the use of the shaky line because it is much easier to hold to the true sweep of a curve with a loose than with a hard line. Full sizing should be learned by measuring off old work, for only so can the sense of the right scale of things which is far more important than their actual form be attained. For full-size details of ornament the softest pencils should be used—speed and

FULL SIZE DETAILING TO SHOW SINGLE HATCHING.
Percy E Nobbs.

sympathy are to be found in a 3 B. Every one will develop his own way of shading, but the advantages of point work are worth considering, and here let me say that shadows are not our business. To my mind architectural details are simply rendered misleading by the projection of shadows in the "Beaux Arts" manner. That is encroaching on the painter's prerogative to represent things not as they are but as they look or might under unlikely circumstances be imagined to look. To detail ornament then we must ignore all the cast shadows. The projection we purpose can be given by sections. The modelling of surface can only be rendered by shading, so let us adopt the most adaptable method of doing this. I have already said "shade with the point," and I must add and "do not rub the paper into a gray scumble." Clean single hatching is the fastest and most suitable of methods. Three ways of differentiating values are inherent in this kind of shading and they make for sympathy in rendering as well as direct and speedy excution: (a) By the wider spacing of the lines any degree of change may be attained. (b) By the use of heavier lines any tone can be presented. (c) By the direction of lines, flow of surface can be indicated.

The simpler and more direct the method to which a draughtsman confines himself, the greater dexterity will be attained in it. The intrinsic beauty of shading

outright once and for all with a single hatching is that so much transparency can be got into the shaded surfaces and with practice any degree of delicacy or violence in modelling can be distinctly set down.

I have here two interesting drawings by an old and successful rival for R.I.B.A. honours, Mr. Bennet.

CHARTRE CATHEDRAL—THE DOORWAY.
From a Photograph.

CHARTRE DOORWAY.
Wash Drawing by Mr. Bennet.

CHARTRE DOORWAY.
Line Drawing by Mr. Bennet.

In the pencil drawing we have things as they are, in the wash drawing things as they look. Suppose the thing were not in existence except in an architect's mind. There is no doubt about which of the drawings would lead to the better execution. The line drawing not only tells far more, but it required greater skill to produce. Blinded as we are by all pervading ideals of the picture painter, we are possibly more attracted by the wash drawing, but looked at closely, a photograph would give us as much, while no photograph could give what the less imposing line drawing conveys of how the effect is got to those who know. I am bound to say that in my opinion the wash drawing should never have been made. In technique it is far better than most of the wash work we see in water colour exhibitions and it is gratifying to possess a copy of it. Faithfully and lovingly it was done, but why should time and skill superior to that of the very carvers who did the original be lavished upon what any photographer could turn out. Mr. Bennet was a student both of the R.I.B.A. and the Beaux Arts and the happy circumstance of the two drawings in the two styles has suggested to me this comparison which I hope will lead to a discussion. As the Beaux Arts methods of draughtsmanship obtain in all the other Architectural Schools on this side the question is of great interest to me.

And here lest I be for a moment misunderstood let me say that my admiration for French draughtmanship is unbounded. These Prix de Rome drawings by students of the Beaux Arts speak for themselves. The delicacy, insight, knowledge and skill of the French draughtsman is something on an altogether different level from our rough English work and I can only envy him his clever fingers. There is much that the English draughtsman would do well to copy from his French brother, especially in the matter of showing nearer and further portions of a building in different strengths of drawing, though I think that scientific sciography is a mixed blessing in an architectural drawing. The French as a nation do draw better than we do, it is born in them more or less, and if our English architectural student were to be trained to the same standard of draughtsmanship I fear he would never learn very much architecture. Moreover when an Englishman draws at all well he is apt to let all other architectural accomplishments take care of themselves.

Putting questions of time and money aside, I am bound to state my own preference for the omission of cast shadows even on competition drawings, although I seldom leave a drawing raw from the inking in without putting in thin washes to emphasize or reduce the values of various parts. This conventional as opposed to scientific sciography is apt to tempt the draughtsman to make things look as he would like them to, not as they really would, but on the other hand the over scientific methods seem to spoil the scale of the drawing. The most important thing to realize from a drawing about a building is its size. The profusely shaded French drawing is apt to look so real on the paper as to suggest a drawing of a little model, not a flat drawing of a very big thing (for even a small house is a very big thing).

In a detail for Mr. Tapper's design for Liverpool Cathedral an attempt was made to render the plans of various parts by tones of color and without any sciography. The drawing was 7 feet long to ½-inch scale and I think a better idea was given of Mr. Tapper's huge conception than if the great masses had been broken up by cast shadows. Even in sketching the architect must ever pay more attention to the thing as it is than the thing as it looks, and I am often amused by the attempts of picture painters to render architectural subjects without searching into the real nature of such things as crockets and double ordered tracery and bed moulds of cornices. Many otherwise fine etchings and engravings fail adequately to get the spirit of architectural subjects simply for want of scholarship.

I have here three beautiful pen and ink sketches by C. E. Mallows, A. N. Prentice and Reginald Bloomfield. In all there is evidence of tremendous skill in epitomising things they know. It is only an intimate knowledge of English crocketed pinnacles that makes it possible for

Mr. Prentice in a few dots to get the very life and soul of St. Mary's, Oxford. Mr. Mallows indicates his brick and tile texture with that sympathy born of knowledge of the thing as it is as well as power to render it as

Pen and Ink Drawing by A. N. Prentice.

PEN AND INK SKETCH.—REGINALD BLOOMFIELD.

it looks, while Mr. Bloomfield's dashing line might be envied by any pictorial artist to whom drawing is more than an incidental professional requirement. Perhaps the most brilliant English draughtsman is Mr. Joass who links the last generation to our own. An immense appreciation of details as they are, have combined with long and arduous practice to give him a felicity of expression which I can only describe as eloquence in drawing. An unfortunate result of his dexterity has been that in a thousand offices his every trick and mannerism is being imitated. It looks so easy to leave all the setting up lines in a perspective where they are and swim some vagrant washes of mellow colour upon a sheet of ochre tinted paper and thereby produce the solemn joyfulness of one of Messrs. Bodley and Garner's great church

Drawing by T. Joass.

interiors with its stately dossal and diapered altar frontal glowing in the amber light which percolates the the stained and traceried windows. As to free sketching however, to the architectural student I would say "beware how you sketch." The more the ego with the skillful hand is suppressed and the more the building with its peculiar qualities is felt, the better. We sketch to understand not to sell. I doubt if any man whose sketches have attained to any character and intrinsic beauty modelled his work on that of others. If a sketch is begun as it often happens with the preconceived intention of making it look like something we have seen elsewhere, the texture quality and colour of the materials to be represented will have a poor chance.

Peter de Hooch was in many ways the greatest of architectural renderers and though his technique is quite out of the question for practical purposes his spirit is wholly worthy of imitation. How he revels in the beauty that is in brick walls and tiled roofs and paved courtyards. Behind his painting of things as he saw them in golden evening light there is the knowledge of the thing as it is.

Before leaving this question of architectural sketching I should like to say that it is rather an ornamental accomplishment. Just the other day I was talking over some sketches at the R. I. B. A. exhibition with Mr. Prentice, and he rather surprised me by saying his Spanish sketches which are so justly famous were a waste of time and regretting that he had not measured more and sketched less while in Spain. It is after all by measuring existing work and by no other means that the student can get the real relation between the thing on paper and the thing in stone or brick.

I think I have now said and shown enough to make it clear that there is a distinctly English school of architectural drawing with characteristics of its own very different from the Academic or Beaux Art practice which has been adopted almost everywhere else. The besetting sin of the English draughtsman is affectation, but really fine originality is occasionally met with. The Ecole des Beaux Arts men on the other hand all draw so nearly alike that individual character has no chance. On the other hand their average work is far better than the average in England.

What I have said of French and English draughtsmanship holds equally of French and English architec-

ture. In France there is a school of work and a very high average of attainment; while in England there is no body of tradition. Every man works with such traditions as please him and he is not taught to make his selection. The result is a deplorably low general average redeemed, however, by a few really great men whose names will go down to posterity with the great roll of "those who fought and sailed and loved and made our world."

In closing, I should like to remind my hearers of the peculiarly subordinate importance of this question of architectural drawing. Once on a day men built far better than they drew. Now it is the other way. Few buildings ever look so well as the drawings promised and I would go the length of saying that what looks well on paper will certainly not do in execution. Alas that the converse of this proposition should not hold good, else the secret of how to design were easy of solution.

DISCUSSION.

Mr. Burke: I am very sorry that the time will not permit any extended remarks in connection with Prof. Nobbs' paper; Prof. Nobbs has given us, I think, one of the most interesting papers that we ever had at any convention. It has been of absorbing interest; and he has brought us face to face you might say with the best men in England in matters of drawing. We owe him a great debt for his kindness in giving us this paper. I beg to move a vote of thanks to him for his paper.

Mr. Gouinlock: I have much pleasure in seconding that vote of thanks.

Mr. Baker: I think this paper should not be passed over without some discussion even if we have to sabrifice a few minutes. Prof. Nobbs comes to us and tells us that if the drawings do not suit us and do not look nice we needn't despair because probably they are better than we think they are. One point in his paper struck me, when he referred to the beauty of the drawings and the work of the Ecole students. I do not think he made clear to the gentlemen here that these drawings are measured drawings and are really better than the work they are intended to represent. I think he should have pointed out that in drawing architects' scales cannot be too good so that the workmen in carrying out the work would be able to follow the lines laid down. I was glad to hear him speak of Mr. A. M. Prentice, a man well known to me. I had the privilege of being closely associated with him in London and I know he is an excellent draughtsman. I hope Prof. Nobbs will return to us and give us a paper later on, and that his stay in Canada will be of long duration.

The President: I know this is a mere formality, but we cannot so very well express what we all feel; the most pleasant thing to me about the lecture is the lecturer; to think we have a man like yourself upon Canadian soil. I congratulate the Quebec Association, with whom you will work most immediately and I congratulate ourselves in at least being your neighbors. It affords me much pleasure to tender you the vote of thanks of the Association (applause).

VISIT OF ARCHITECTURAL STUDENTS TO THE SCHOOL OF PRACTICAL SCIENCE.

On the afternoon of Saturday, February 13th, the Engineering Laboratory of the School of Practical Science was opened to the senior class students of the Ontario Association of Architects. Facilities were placed at their disposal for a series of tests on the strength of materials. A pleasant and profitable couple of hours was spent at the machines in the laboratory making experiments, illustrating the characteristic behaviour of material when subjected to stress. Tension tests were made on steel, compression tests on long and short parts, and transverse tests on cast iron and on long and short wooden beams. After the tests were completed a short time was spent in examining other testing machines, and a large number of specimens of material that had been tested. Thanks are due to Prof. Wright for affording the students the opportunity of visiting the school.

THE NEW PRESIDENT OF THE P.Q.A.A.

Mr. Jos. P. Ouellet, President of the Province of Quebec Association of Architects, was born at St. Fidele, Charlevoix County, Que., on the 22nd of October, 1871. He is the son of Cyrias Ouellet, now mayor of Kamouraska, Que.

The son of a contractor, from his early years he has shown a marked disposition for the art of building.

He entered Levis College in 1884, and after a brilliant course of classical studies, studied science at Laval University.

In 1889, he began to study Architecture with Messrs. Tanguay & Vallee, and in January 1893, graduated as an Architect, after having attained the mention "Summa cum laude." He worked in his patrons' office for two years, and in 1895 opened an architect's office at Quebec, where, after eight years of hard work and perseverance, he has secured a large clientele.

MR. JOS. P. OUELLET,
President of the Province of Quebec Association of Architects.

He always took an active part in the management of the P.Q.A.A. For six years past he has been Secretary of the Quebec Section, and for three years a member of the Council of the Association, the last of which, as 1st Vice-President. He is now at the head of his profession at the age of thirty two.

Mr. Jos. P. Ouellet has spent the whole of his life at the study of his profession, and as a pastime, has taken an active part in military matters in Quebec. He is one of the best qualified officers of the Canadian Militia, having a long course infantry certificate, and passed the Royal Military College staff course at Kingston. He is very popular in Quebec, as Major in the 9th regiment, "Voltigeurs de Quebec," as well as brigade Major of the Xth brigade of infantry.

Major Ouellet counts a good many friends in Toronto, where he spent three months at Stanley Barracks, attached for a course in the Royal Canadian Dragoons. It may be added that he is a bachelor in arts as well as in private life.

MASTER PAINTERS AND DECORATORS.

The convention of Master Painters and Decorators of the United States and Canada held in Toronto a fortnight ago was a most successful one. There was a large attendance, especially of delegates from the United States. A number of interesting questions and papers affecting the trade were discussed as per the programme printed in January number. The attractively arranged exhibits by manufacturers of materials, gave added interest to the meeting. The proceedings terminated with a ball at the King Edward Hotel. An outcome of this convention has been the organization of a Canadian Master Painters' Association, of which Mr. J. M. Faircloth, of Toronto is the president.

THE BALTIMORE FIRE.

Mr. Theodore Starrett, of New York, whose firm have made a specialty of building sky scrapers, as the result of an investigation on the scene of the Baltimore fire states: That steel frames stood the test well; that practically no harm was done a steel structure where it was adequately protected by bricks, cement, or "hollow blocks"; that of the building materials, stone, brick, terra cotta, and "hollow blocks", brick endured far and away the most satisfactorily; that plate glass did not impede the fire at all; melting and exposing the interior early; that every web in "hollow blocks" is an additional protection; that concrete stands the test best of all fire-proofing materials; that terra cotta is easily destroyed.

The death is announced of Mr. King McC. Arnoldi, architect, of Ottawa.

PROVINCE OF QUEBEC ASSOCIATION OF ACRHITECTS' ANNUAL CONFERENCE.

The meeting place this year was the Chateau Frontenac, Quebec, and the conference was attended by some 25 members, of whom about half journeyed down from Montreal to be present. The following persons were in attendance: W. E. Doran, J. S. Archibald, Prof. P. E. Nobbs, W. J. Carmichael, D. R. Brown, C. Bernier, R. P. Lemay, J. P. E. Dussault, C. Baillarge, Thos. Raymond, A. Levesque, A. H. Larochelle, E. B. Staveley, G. E. Tanguay, A. Chausse, J. E. Vanier, J. A. Karch, Jos. Venne, J. H. Lebron, J. P. Ouellet, J. E. Larochelle, S. Finley, Raoul Lacroix, F. X. Berlinquet.

Shortly after half past ten W. E. Doran, the president, took the chair. The minutes of the last annual meeting held at Montreal on January 27th, 1903, were read and approved and also those of the special general meeting held on November 14th of same year.

The annual report of the Council was then taken as read and adopted on the motion of Mr. Tanguay, seconded by Mr. Karch.

The Treasurer's report was similarly disposed of in the motion of Mr. Lemay, seconded by Mr. Bernier.

The election of office bearers was then proceeded with and the following is the result: President, Mr. J. P. Ouellet; 1st Vice-President, Mr. J.S. Archibald; 2nd Vice-President, Mr. A. Chausse; Secretary, Mr. J. E. Vanier; Treasurer, Mr. D. R. Brown.

Members of Council—Messrs. W. E. Doran, R. P. Lemay, J. Z. Resther, W. J. Carmichael, A. A. Cox and Jos. Venne.

The auditors appointed for the following year are Messrs. L. Lemieux and P. E. Nobbs.

Mr. Doran then congratulated the new President and after thanking the retiring Council for their support during his term of office moved the new President to the chair.

Mr. J. P. Ouellet in the chair then rose to thank the members for the honor done him and paid a graceful tribute to the energy of the retiring President and referred to the arduous legislative business of the coming session.

It was then moved by J.S. Archibald, seconded by Jos. Venne, that the following amendments be made to Section Eight of the By-laws.

(a) At the end of the fourth paragraph after the words "Matriculation fee" add "Of ten dollars."

(b) In connection with the fifth paragraph, erase that section of the paragraph after the word "Accompanied" at the end of the third line and substitute the words "By the registration fee of $25.00."

(c) In connection with the sixth paragraph, add at the end of this paragraph the words "Should the candidate fail to present himself for examination, he shall forfeit the sum of $5.00."

(d) In connection with the eighth paragraph after the word "Acoustics" at the end of this paragraph, add the words "Specification of works."

(e) In connection with paragraph nine, omit that part of the paragraph after the word "Examiners" at the beginning of the seventh line, and subatitute "In the event of the candidate not being admitted to the examination, no portion of the registration fee shall be forfeited."

(f) Insert the following between paragragh nine and ten: "The Board of Examiners shall report to the Council on the result of the examinations at the regular meetings of the Council for March and September respectively. The Council shall notify candidates of the result of the examinations within eight days following the adoption of the Exminers' report." Mr. Archibald made it clear to the meeting that there was no new principle involved but that the changes in the wording of various clauses were designed to make them more harmonious. At the same time he stated, the Council had prepared in accordance with the resolution passed at last annual meeting, a pamphlet for the guidance of candidates. These proposals were adopted.

It was next moved by Mr. W. E. Doran seconded by Mr. J. S. Archibald to add to bye-law 8th:

"Candidates for admission to registration as architects who have graduated from recognized schools or colleges of architecture after a full course of four years and who shall present certificates of having successfully passed in such schools or colleges in their final examination, for any of the subjects prescribed by this bye-law shall be exempted from further examination in such subjects."

Mr. Doran in introducing this motion pointed out that this motion proposed a slight extension of the principle of recognizing standards of examinations held by other bodies already admitted. Subjects in which the P. Q. A. A. examined and not covered by the work of graduates of Architectural Colleges would be still enforced, while the question of whether a college be recognized or not remained in the hands of the Council.

Mr. Lacroix moved that the question be referred to a Committee appointed by the Council; as it was too serious to be disposed of at a general meeting.

Then Mr. Venne objected to the principle of the motion, holding that the Association should have absolute control of its qualifying examinations. He admitted that the standard at present was low and would have to be gradually raised.

Mr. Lacroix was permitted to speak a second time. In warmly supporting Mr. Venne's attitude his main contention was that the dignity of the Association could best be assured by keeping the control of the examinations.

Mr. Nobbs then rose to speak in support of Mr. Doran's views but to second Mr. Lacroix's amendment as he deemed the matter should not be settled out of hand. In so far as this motion affected McGill he reminded the Association that it was at their instance that a School of Architecture had been started there and a great deal of money had been spent on equipment and endowment. That school had now passed through the stages that all architectural schools on this side pass through—the stages of too close connection with the engineering college that gave it birth—and he was able to announce that a purely Architectural Course and the degree of Bachelor of Architecture had been embarked upon. The proposal of Mr. Doran would be of great benefit to McGill as an inducement to students of architecture to study there and therefore for the good of the profession. The Association existed for two purposes—for the advancement of the study of architecture and for the regulation of professional conduct. Its existence as a close corporation was a mere incident of these high purposes.

Mr. Nobbs then proceeded to compare the standards of Architectural education required for the R. I. B. A. final by the American Colleges of which he had made a special study and by the Association and stated that there was no comparison possible between the Association standard and that of the Royal Institute and the American Colleges with which McGill would now be ranked. In conclusion Mr. Nobbs said he would be pleased to see the graduates of McGill Architectural school required a longer term with a principal after leaving college and before presenting themselves for admission to the P. Q. A. A., and he would gladly see a design required of them by the P. Q. A. A. but he had the greatest objection to their being compelled to take examinations in subjects already passed on a higher standard and he did not think it was to the interest of the Association that they should do so.

The meeting then adjourned for Lunch.

At 2.30 the President again took the chair when Mr. Archibald continued the discussion, with a view to ventilate opinion on the subject. He reminded the Association that they had set $600 aside to put a student through the McGill course and asked if that would have been done if as good training could be had outside its walls as inside. Moreover he knew that that University had been largely drawn upon for examiners for the Association and endorsed Mr. Nobbs remarks as to the low standard hitherto required by the Association, which must be raised. After citing cases in which members of the American Institute of Architects had been admitted to the Association and referring to the rule by which members of the R. I. B. A. and of the O. A. A. were admitted while all graduates of Universities were exempted from the Association Preliminary examination, he argued that the principle of Mr. Doran's motion had long been established of adopting equivalents to the examinations. Moreover the motion before the meeting left it entirely in the hands of the Council what colleges should be recognized.

Mr. Belinguet then spoke a few words on the practical nature of all architectural training and while agreeing with what had been said on the matter of standards and examinations felt that it was in the office alone that the architect could learn much that was vital.

The meeting then adopted the amendment referring the matter to a committee nominated by the Council and to include the proposer and seconder of the amendment and to report at the next general meeting.

Mr. Doran laid before the meeting a letter from Mr. E. Maxwell strongly objecting to the present tariff and urging a

universal 5 per cent. for first-class work, regardless of size, and 10 per cent. on fittings, etc., and reminding the Council of last year that this matter had been handed to them to deal with and that nothing had yet been done. Mr. Doran explained that the Council and members of the Association were as strongly opposed to points in the present tariff as Mr. Maxwell but that they felt some tariff legally recognized was better than none and that it was not desirable to ask for legislation every year. After an animated discussion in which Messrs. Baillarge and Vanier took part a motion was adopted, proposed by Mr. Venne seconded by Mr. Brown, "That without recognizing the assertion of Mr. Maxwell that the Council paid no attention to the question of amendments to the tariff; that the said letter be referred to the Council with instruction to study the question and to report at the next annual meeting."

Mr. Venne, seconded by Mr. Archibald, then brought in a scheme of awarding medals to various classes of work with a view to stimulating artistic effort and rewarding skill. The scheme dealt with domestic, public and ecclesiastical awards of merit, the former being that on which most stress was laid, as Mr. Venne deplored the condition of domestic work in the towns of the province generally. Mr. Berlioguet criticised the scheme and Mr. Lemay spoke in support of it, after which the question was remitted to the Council to be given effect to.

Mr. Venne, seconded by Mr. Tanguay, called the attention of the Association to the state of competition management in the Province which gave rise to many misunderstandings and proposed that the Council make a study of the customs of other countries in this connection and frame a set of by-laws calculated to prevent abuses as far as possible.

Mr. Lacroix next called the attention of the Association to the unprofessional practices which appear still to obtain in the province with regard to rate cutting and the preparation of plans free as means of canvassing for work. Mr. Berlioguet did not agree with the first speaker that it was possible to draw a hard and fast line with one's clients to whom an architect may justifiably desire to do a favor, though against competitive rate cutting he felt as strongly as any one present. Mr. Venne quoted a case in which when a building was burnt down 21 sets of drawings were supplied to the owner by members of the profession unsolicited. The sentiment of the meeting was wholly against such practices.

Mr. Chausse, seconded by Mr. Vanier, moved that a special committee be appointed by the Council to amend the charter and by-laws relative to the election of office bearers and to report at the next general meeting. This was agreed to.

Mr. Chausse moved that a year book be issued containing the charter, by-laws, calendar, tariff code, and papers read before the Association. Mr. Archibald seconded the motion provided "if means could be found" were inserted, as he said the financial state of the Association was the only drawback to such a scheme. Messrs. Brown, Baillarge and Karch supported the idea and the motion as amended was remitted to the Council to be dealt with.

Mr. Chausse, seconded by Mr. La Rochelle moved that a badge be designed and worn by members. After some discussion of a desultory nature the matter was dropped.

Mr. Karch proposed that the Council take action to urge on the Government the necessity of legislative measures for the arbitration of trade disputes. The proposal failed to find support.

Votes of thanks were then moved, seconded, and heartily accorded to last year's Council for their labors, to Mr. Larochelle and Mr. Finley for acting as scrutineers, and to the management of the hotel for the use of the Empire Room for the Exhibition.

The president then complimented the Association on the exhibition which had been got together and reviewed the work of the coming session.

Mr. Venne, seconded by Mr. Archibald, moved that the next annual general meeting be held at Montreal.

This was all the business.

P. Q. A. A. EXHIBITION.

The exhibition of architectural work displayed on the walls of the Empire Room at the Chateau Frontenac, Quebec, in connection with the P. Q. A. A. Conference, while presenting some features of interest, is on the whole disappointing when one thinks of the glorious building traditions of ancient France which in this province one might still hope to find manifesting themselves either as survivals or as revivals. Domestic work was all but absent; of public buildings there was little to be seen; city offices were fairly numerous and represented the best body of work, while though there was much church work it was not of a high order of merit. Taking the church work generally the classic examples were far ahead of the Gothic efforts. A tendency is to be noted in a good many of the church designs to lavish all the ornament and embellishment on the Western facade and to carry out the rest of the building in the baldest way.

From Mr. Vanier's office there were several drawings and photographs. The Classic Church of St. Jean Baptiste, Montreal, though open to criticism on the score above alluded to shows some sound scholarship. It is a pity that the porch had not a deeper projection and that the lantern on top of the dome is so very small; the octagonal flanking turrets at the west end are very satisfactory. There is a considerable feeling for picturesque grouping in the Hotels de Ville designed in the Francois I style from the same office.

Mr. Payette shows us a dainty set of drawings for a romantic house in brick and stone with a half timbered third storey and picturesque pavilion roofs with sweeping bell casts.

Mr. Venne presents a clever pencil drawing for a library facade in what may be called the Ecole des Beaux Arts style of French classic. The design would be the better of more weigth at the angles of the projecting centre where there is no abutment worth mentioning for the heavily rusticated arches of the window openings.

Mr. Resther exhibits a drawing for the great Pensionnat de Ste. Nom de Marie, Outremont, in a somewhat stereotyped classic style but a sound building nevertheless.

Messrs. Finley & Spence have a perspective of the Guardian Building, Montreal, a somewhat ornate city building and a very beautiful drawing illustrating a design for the City and District Savings Bank. The design for the Montreal Athletic Association Club House appears less refined than the rest of their work.

Messrs. Hutchison & Wood illustrate the London, Liverpool & Globe Building, Montreal. As a whole this building is a happy solution to the "city building" problem, but it is not improved by the very coarse decorations with which it is adorned.

Mr. Baillarge exhibits an old scheme for a Parliament House dating from about 1660. The elevation shows a great Corinthian colonnaded facade, reminiscent of the Louvre. He also shows decorative designs in which a sincere and successful effort to design ornament with some symbolical meaning is manifest.

Mr. Tanguay's project for a great Late Romanesque Cathedral church at St. Hyacynthe is striking. The fleche of a very late Gothic character is hardly in tune with the rest.

Messrs. Staveley and Staveley show a block of houses for Park Avenue which is one of the soundest pieces of design exhibited.

Dr. Doran illustrates the Catholic High School, Montreal, receotly completed, and a design for a Bank in a pure classic Ionic

Mr. Venne has some church work in which the detailing shows much thought and some bold originality.

Mr. Stone shows some severe office buildings, in which breadth is the main element of charm; and very refreshing and bold they are in these all too ornamental days.

Mr. Taylor's branch banks in a pure classic style come somewhat as a surprise to those accustomed to his work on a Byzantive basis. He also submits some charming student sketches of Italian clock towers and belfrys and photographs of the triumphal arches he designed to celebrate the visit of the Duke of York.

Mr. D. R. Brown has a perspective design of the Olivet Baptist Chapel, Montreal, a building what may be called Modern Gothic atyle in brick and stone and certainly the best example of Gothic architecture in that City, the amended design being a decided improvement on this first sketch.

Messrs. Saxe & Archibald show an elevation of the Bellview Flats, Montreal, a tall apartment building in yellow and red brick and some picturesque cottages at Westmount.

CORRECTION

The illustrations of Ospedale Maggiore, Milan, and Mosaic Pavement, Ravenna, printed in the CANADIAN ARCHITECT AND BUILDER for January, were reproduced from drawings by Mr. Cecil Burgess, but were wroogly credited to Prof. Nobbs.

We are indebted to Mr. Burgess for the following descriptions:

OSPEDALE MAGGIORE

The Ospedale Maggiore or Great Hospital of Milan is one of the most interesting architectural works in that city. It is one of the largest as well as one of the oldest institutions of the kind in the world. The principal facade of the building belongs to the middle of the 15th century at which time the hospital was founded. Of nine courtyards which the buildings enclose the largest and most splendid is the immense central one over 200 feet square, built, by Ricchini, in the early part of the 17th century. A portion of this courtyard is here illustrated. It is entirely surrounded on the ground level by an open loggia, or wide vaulted passage, presenting to the courtyard an arcade of 17 arches on each side. The first floor consists of somewhat similar loggia, portions of which, however, are enclosed by a screen wall with beautifully designed windows.

The materials are remarkable. The pillars on both stages are monoliths of grey granite, with granite bases and terra cotta capitals. The plain wall surfaces are of brick, plastered and coloured yellow. The molded and decorated work is all of pale red terra cotta which, though more than two centuries and a half old, is in perfect preservation. The modelled panels of both upper and lower friezes contain a wonderful variety of design. It is difficult to detect repetitions. The first floor windows have sparred wooden shutters. The crowning entablature which is proportioned to the total height of the facade is designed with consoles dividing the frieze into panels and giving support to the large modillions of the cornice.

This is probably the most important work of the Renaissance executed in terra cotta. Not far from Milan the cloisters of the Certosa, of Paira, give a splendid example of mediaeval terra cotta work. The earliest part of the Milan Hospital is also a fine example of terra cotta work of a curiously transitional character.

PAVEMENT AT RAVENNA

This marble pavement of Roman workmanship was found in 1875 near the Basilica of St. Appolinare in Classe, a few miles from Ravenna, and is now preserved in the Accademia delle Belle Arte in Ravenna. The vase below the peacock is a fragment of a Byzantine mosaic which has been inserted into the old Roman one.

TORONTO BUILDERS' EXCHANGE DINNER

A very successful dinner under the auspices of the Toronto Builders' Exchange took place in McConkey's restaurant, in Toronto, on the evening of the 23rd inst. An innovation was made this year by inviting ladies, the wives and friends of the members, whose presence added attractiveness and interest to the occasion.

The newly organized Brantford Exchange was represented by Mr. Whittam. It was a subject of regret that the Exchanges in London and other cities were not also represented.

Mr. R. G. Kirby, the newly elected President of the Toronto Exchange, presided, having on his right the Mayor and on his left Mr. Thos. Crowford, M.P.P. The vice-chairs were occupied by Messrs. J. R. Hoidge, Henry Martin, Geo. Duthie, Thos. Christie and James Munroe.

The excellent menu was prefaced by the following specification:

"Trust not too much in new friends and old houses"

Specifications of materials to be supplied and labor to be furnished at the Annual Banquet of the Builders' Exchange, February 23rd, 1904

GENERAL CONDITIONS

Parties estimating on this work to pay for Bill of quantities before they will be allowed to tender. Members of Board of Control, Aldermen or Civic Employees will not be allowed to compete.

TIME

Time will be the essence of this contract. The whole works must be complete in every particular and handed over to the proprietor on or before 9.30 on February 2 rd, 1904, in order to make way for decorative artists of Oratory and Music.

CONTRACT

The form of Contract will be the Revised Builders' Contract No. 2.

Section 2 of this contract provides that the contractor must give this work his personal attention and must not sub-let any part of the work.

Section 4. Should the proprietor or architect require any alterations of, or deviation from this specification they shall pay for same at time of change and avoid disputes later on.

Section 4. Should the work not proceed fast enough the contractors will not be allowed to quote the Street Railway as a precedent for further delay.

Section 5. All disputes to be settled by arbitration

Section 6. Re-insurance; the proprietor shall insure the contractor against any damage or loss of time through this contract.

CUTTING

Each department of trade to do their own cutting.

MATERIAL

To be the best of their respective kinds and any material delivered on the job to be the property of the proprietor. No material such as spoons, forks, etc., to be removed without the order of the superintendent in charge.

FOUNDATION

Great care must be taken to prevent frost interfering with this work for at least three days previous to commencement of operations.

"He that buys a house ready wrought,
Buys many a plank and nail for naught."
"What, do we meet together?
Ay, and I think one business doth command us all."

The National Anthem having been heartily sung in response to the toast to The King, the Mayor responded to the next toast "Our City," proposed by the chairman. He dealt with the importance of civic affairs affecting as they did the pocket as well as the health and happiness of every citizen. As showing the growing importance of the city, he stated that the revenue of the Toronto post office this year reached a million dollars, being 30 per cent greater than that of Montreal and that the city's proportion of street railway receipts had increased nearly three times in ten years.

"Our Country," proposed by Mr. J. R. Hoidge was replied to by Mr. Crawford, M.P.P.

In proposing "The Architectural Associations," Mr. Henry Martin urged that the relation between architects and builders should be more intimate and sympathetic than in the past. He referred also to the desirabilit of architects adopting a uniform contract. At present every architect has his own form, and in many cases the builder signs it without knowing its provisions, only to find later on that he has bound himself to do more than he had any idea of.

Mr. Sproatt, replying on behalf of the Toronto Architectural Eighteen Club, said that builders should refuse to sign a contract the terms of which were not satisfactory. They should also demand a fair price for their work in order to maintain a proper standard of workmanship. Speaking from the architects' point of view, he believed modern demestic architecture in Toronto was equal to that of any other city on the continent.

Mr. Siddall, representing the Ontario Association of Architects, in the unavoidable absence of Mr. Gemmell, the President, corroborated Mr. Sproatt's estimate of the quality of domestic architecture in Toronto. He sympathized also with Mr. Martin's plea for more friendly relations between the architects and the builders; the latter, in the present day at least, were endeavoring to do honest work, and cases of sins of willful commission were rare. He regretted the great waste occasioned by labor disputes, and hoped that the legislature, which was understood to have the subject under consideration at the present session, would be successful in devising a remedy.

Mr. George Duthie, in humorous terms, proposed "Sister Organizations." Mr. Whittam, of Brantford, on behalf of the Exchange of that city, thanked the Toronto Exchange for assistance given the younger organization which he represented, and remarked that their aim was to elevate the standard of workmanship so that their work might express to future generations the integrity and skill of the builders of to-day.

Mr. Locke responded on behalf of the Toronto Master Painters' Association, referring to the benefits accruing from the recent convention in Toronto of the Master Painters and Decorators of the United States and Canada.

Mr. Thos. Christie proposed "The Press," and Mr. James Munro "The Ladies."

In addition to Glionna's Italian Orchestra, the following well-known artists contributed to the evening's enjoyment: Miss Mildred Stewart, contralto; Mr. Owen A. Smiley, entertainer; Mr. Arthur Blight, baritone; Mr. W. F. Tasker, accompanyist.

To the following gentlemen composing the Dinner Committee the success of the occasion is largely due: Henry Martin, chairman, J. B. Thompson, R. G. Kirby, Geo. Duthie, James Crang, Walter Davidson, Alex. Marshall, Jos. Russell, J. R. Hoidge, secretary.

AN IMPROVED DIRECTORY FOR BUILDINGS.

The question of a Directory or Bulletin in front of large office buildings, is one of the utmost importance. Some of the finest buildings are spoiled by the unsightly wooden, glass and brass bulletins, which always look incomplete, as in most cases unless the building is fully occupied, there are a few spaces missing.

The signs are usually made by several painters, and brought from other buildings, and are always thrown together any old way, making anything but a neat entrance.

Most of the large buildings put up the last few years however, have had the advantage of the changeable directory, arranged alphabetically, which is put on the market by The Martel-Stewart Co., of Montreal. There are some beautiful examples of this directory in the Grand Trunk Railway, Montreal, Liverpool, London & Globe Building, Guardian Assurance Building, Canada Life Building, and in fact in the majority of the large buildings in Montreal and other Canadian cities, as well as in the United States and Europe.

The cut here shows what one would suppose would be a finished directory, and although it is, there still could be over 100 names put on without crowding same, and twenty-five names could be taken out, and still the directory would look complete.

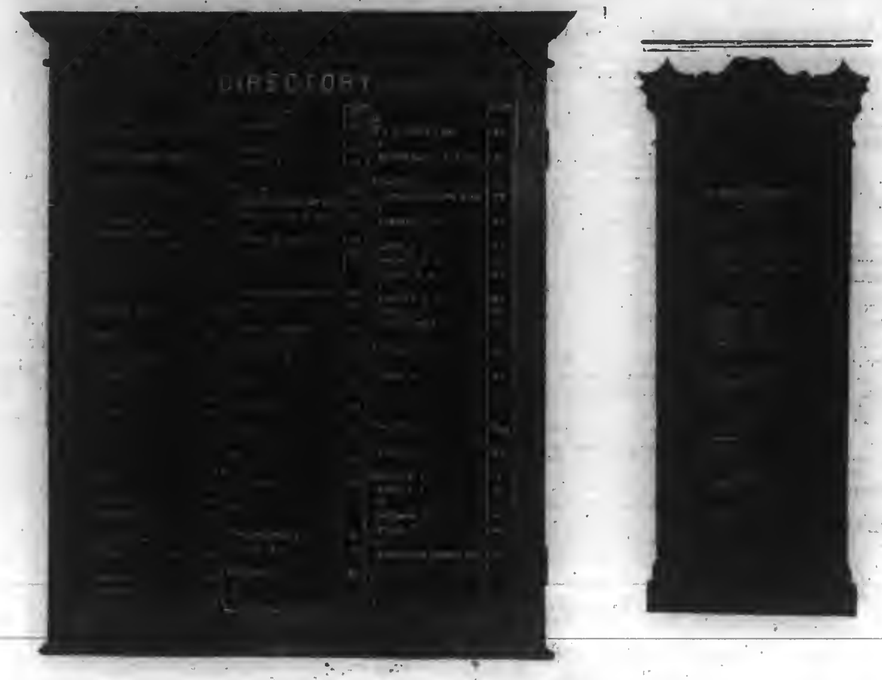
The result is obtained by the use of a grooved background covered with a dark cloth, in which white celluloid letters with a V spring on the back are placed in the proper positions, forming the names. When it is necessary to change the names, it can be

done by the janitor of the building in a few minutes. This makes the directory always appear properly, and is a great improvement on the old style office directories, which are even now being put up in some of what are otherwise modern buildings.

The following are a few examples of what are seen :

The marble slab lettered in gold with black seems to be the most popular, but after they have been lettered a couple of times by different painters, they have such a poor appearance and such a medley of different styles of type, that they are an eyesore to the entire building. The polish of the marble also wears off from constantly cleaning the paint off.

On directories lettered on glass, it is almost impossible to make a nice job, and in most cases the directories have to be removed to be altered every time a new tenant comes into the building. This is a great source



of annoyance as it deprives the other tenants of their names being on the directory while it is away.

The wooden directory with black panels and white letters, is another sample of a poor office directory, as after it has been changed a few times, one half of the directory appears to be new and the other half old.

With none of these directories is it possible to keep the alphabetical arrangement, which is almost absolutely necessary for quick finding of any names.

There is also a changeable directory, in which little paper letters are pasted on card, and inserted in a frame with glass over. These are rented by the firm who makes them, and every time a new name is wanted, it is a matter of several weeks waiting for the name from New York, and re-arrangement of the whole directory.

The plan adopted by all the large buildings seems to be almost the same plan of this cut, naming the offices in the basement of the building either, A, B, C, D, or B-1, B-2, B3, etc., and then above numbering as follows :

Ground Floor	1 to 99
First Floor	100 to 199
Second Floor	200 to 299
Third Floor	300 to 399

Or in event of there being less than ten offices on each floor, they sometimes read,

Ground Floor	1 to 9
First Floor	10 to 19

and so on up to the top.

By arranging the letters alphabetically, it is easy to find a name at a glance, and if the number of a man's room is 213, the elevator man knows at once that it is on the second floor, and really never requires much thinking on the man's part who is looking for a certain tenant, that the office was on the second floor, and that the first number denotes the floor the office is on.

The frames of these directors can be made in a great variety of styles. In the North British and Mercantile Building in Montreal, there is one of these directories with a very handsome green marble frame.

The directory in the Grand Trunk Railway offices, McGill St., Montreal, on the main floor, has a natural oak frame, hand polished, set in wrought iron easel, the whole costing upwards of $1,000.

The directories, however for an ordinary building are quite reasonable in price, costing according to their size and number of letters, etc., from $50.00 to $200.00.

These directories are not only used for office buildings, but have been used by stock exchanges for quotations, Steamship Lines for S. S. sailings, Military organizations, Hotels, Hospitals and also in Churches to denote Pew Holders. In fact the uses are unlimited.

The small cut on this page represents a brilliant idea for changeable directories, denoting the heads of the different departments in a factory, bank or office of any kind. This has an imposing effect on customers entering the office where it is placed. It is also a great time saver, as people coming in know from the Bulletin who to inquire for in the different departments.

There are a great many times in offices, where the wrong party is called from his work, and comes down a couple of flights of stairs, and finds that it is not he who is wanted, but the head of another department.

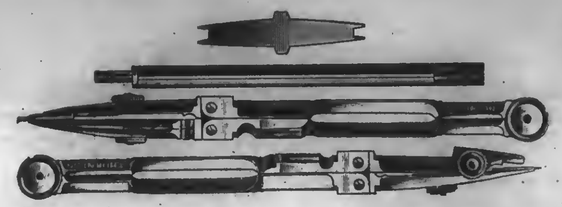
The Martel-Stewart Co., of Montreal, are the makers of this directory and will give all further information with pleasure.

British Trade Supplement

THORNTON'S

Improved English Drawing Instruments

6 in. Pen and Pencil Compasses, either with or without Lengthening Bar, as illustrated;



fitted with Thornton's Patent Combo Needle Points allowed to be the best and most satisfactory yet introduced.

Half Sets from 3s.
Bows - - - 2s.
Spring Bows 5s. 6d.; set of 3.

Dividers from - - 2s.
Drawing Pens - 1s.
Beam Compasses from 9s.

Proportionals, Napiers, Pillars, etc., etc., in great variety.
Repairs Done Neatly, Expeditiously and at Moderate Rates.

THE BEAUFORT CASE

The above is my latest ; it comprises a fully complete set of Best Extra Quality English Electrum Instruments, with all most recent additions and improvements, in a flat Real Morocco Pocket Case, and the case when closed only measures 5½ inches long by 3 inches wide. The bulk of my cases are all quite special and entirely different to what are usually sold. For particulars and prices see Illustrated Catalogue —post free.

SPECIAL SURVEYING INSTRUMENTS

ENGLISH MAKE.

LEVELS with Case, Tripod and Fittings Complete from 70s.

THEODOLITES, STAVES, CHAINS, TAPES, RODS, ETC., in large variety.

TRACING PAPERS AND CLOTHS of every kind and quality, also PHOTO PAPERS for copying tracings. Samples post free.

NEW DRAWING BOARDS AND T SQUARES.

LIQUID WATERPROOF COLOURS, PENCILS, RULES, SCALES, ETC., ETC.

Just Published—Enlarged Edition of Catalogue (A 1903) Demy 8vo 240 Pages, over 500 Illustrations and 18 full Page Coloured Illustrations. Post free.

NOTES.

A well-known Venetian engineer, Signor Vendraso, states that the tower of San Giorgio Dei Greci is in danger of falling. This fine campanile, which is nearly 200 ft. in height, is more than 400 years old. The inclination of the tower, which was observed to be about 18 in. in 1889, has been slowly increasing, until now it is more than 3 ft. out of the perpendicular. In his opinion the campanile must soon succumb unless immediate measures are taken to restore it.

Uniform Building Laws. The International Society of State and Municipal Building Commissioners was recently organized in the city of Washington. One of the purposes of the Association is to secure a greater degree of uniformity in building regulations. The object is praiseworthy, and one that we hope to see achieved. The combined experience of a large number of cities in relation to the most satisfactory methods of constructing buildings, to ensure safety and reduce the fire risk should be embodied in a standard set of regulations that should govern the construction of important city buildings in the future.

Vancouver Warned. A letter appears in the Vancouver papers over the signature of Mr. Henry Lye, a well known fire insurance adjuster, protesting against the proposed erection in the heart of the city of a wooden building of immense size, which must prove a source of danger to the more substantially built structures surrounding it. In 1886 Vancouver was laid in ruins by fire. Is a period of only seventeen years sufficient to efface the memory of such a catastrophe and destroy the lessons it should teach? While the adoption of the severest restrictions in force for the prevention of fire in metropolitan centres might be calculated to hinder the development of young cities like Vancouver, building in such cities ought nevertheless to be subject to reasonable restrictions. This especially applies to the business district, in order that none but buildings of substantial construction and appearance may be put up, and that the appearance of the principal thoroughfares may be pleasing and impressive and a barrier placed in the way of the spread of fire. A city of the size and importance of Vancouver ought to have build-restrictions of some kind, and any kind should be sufficient to prevent the erection of a fire trap in the centre of the business district.

The Water Supply of Toronto. The property owners of Toronto have shown wisdom by voting in favor of the by-law submitted for their approval on the 23rd inst. to authorize the expenditure of a million dollars for improving the public water supply. The city has entirely outgrown the present system and from the standpoint of health as well as of fire protection, demands that the capacity of both pumping and distributing systems be largely extended. During the present winter the city was brought almost face to face with a water famine, and much destruction of property must have resulted if a serious fire had occurred during the time when there was but little pressure on the mains. There are some things a city may do without, but an abundant supply of pure water is an absolute necessity

and ought to be provided regardless of cost. A great mistake was made when a year or two ago the charge to consumers for water was cut in half. In consequence of this cut the revenues of the water department have since fallen short of the expenditures by more than $75,000 per year. This deficit has to be made up by the property owners, who were therefore not as favorably disposed to vote the money now required for improvements as they would have been had the department remained on a self-sustaining basis. In view of the urgency of the case, however, it is gratifying to note that a broad view of the question was taken, and the authorities put in position to carry out the improvements.

The Building Outlook.

It is perhaps too early to speak with certainty regarding building enterprises likely to be undertaken during the season now opening. The information at hand, however, would indicate that taking into consideration all sections of the country, a fairly brisk season is in prospect. So far as can be learned it would appear that the numerous and serious labor difficulties which were a marked feature of last season and which reduced so materially the income of both contractors and workmen, are not likely to be repeated this year. Agreements have already been reached in some trades and it is to be hoped that soon after the first of April, all possible causes for disagreement will have been adjusted and removed out the way. In New York the plan has been introduced of dating wages agreements from the first of January instead of as heretofore from the first of May. A sufficient number of unions have already given their assent to the change of date to insure the success of the movement. The change is a most desirable one and must work to the advantage of all whose interests are in any way dependent on the prosperity of the building industry. The builders and building workmen of Canada should lose no time in adopting similar action, thereby getting rid of the uncertainty which in the past has usually prevailed at the opening of every building season. This uncertainty and the recollection of last year's experience may have something to do with the fact that so far contractors in Toronto have been asked to do but little tendering.

The tightness of the money market may to some extent have a retarding influence upon building this year, but speaking generally, the prospects point to a fairly active season in Toronto. In Hamilton a repition of last year's activity seems certain, the leading architects' offices being crowded with work much earlier in the year than usual. The erection of the immense new factories of the Deering and Westinghouse Companies giving employment to thousands of skilled workmen, has created a large and immediate demand for moderate cost dwellings. Throughout western Ontario much building is said to be also in prospect. In Winnipeg and the West as well as in the Maritime Provinces all indications point to a record year for builders.

In the United States lower prices are expected to prevail. Mr. J. Knox Taylor, Supervising Architect, is quoted as saying that during the past few months there has been a drop in tenders amounting to upwards of 20 per cent. and he looks for still lower figures. He further states that there is now keen competition for government work, while a year or so ago bids were comparatively few. In Canada prices for labor and materials are likely to correspond closely with those of last year. While the output of lumber will be considerably reduced, the slackening of demand from Great Britain and also from the United States, due to the disturbance to trade caused by the approaching Presidential election, will likely prove an effective offset to any advance in prices.

The Baltimore Fire.

Since the recent great fire Baltimore has been crowded with visitors, principally architects, contractors and experts. The architects have been looking for information, and many of them for commissions. The contractors are on the look-out for contracts, while the building experts, including many city architects and building inspectors, have visited the scene with the object of observing the effects of the conflagration upon the various kinds of building materials and methods of construction. One fact stands out prominently as the result of this fire, namely, that steel buildings when properly protected by fire-proof materials, such as porous cotta and reinforced concrete are able to withstand a severe fire. But for the fact that several steel structures stood in the way and blocked the progress of the fire, the public buildings and a large section of the residential district of Baltimore would have been destroyed. This fire has further emphasized the necessity of protecting by means of iron shutters, wired glass, or other equally effective methods, the windows of large buildings in the business centres of cities.

The Mayor of Baltimore has appointed a committee of citizens to advise concerning the reconstruction and improvement of the burned district. The existing building by-laws of the city will be carefully revised and remodelled before any new buildings are allowed to be erected. It is proposed that all new buildings over 100 feet in height shall be fire-proof throughout; that stores and warehouses more than two storeys high be equipped with fire-proof shutters on all windows not opening on a principal thoroughfare; that all outside walls shall be build of stone, brick, iron, or other non-combustible material, and that the roof sheathing shall not extend across front, rear, side, end or division walls. It is proposed to establish a municipal experimental testing department for the investigation of materials by the department and by builders and contractors.

BANK OF MONTREAL, SYDNEY, C.B.

The position of this building, illustrated in the present number, is in the centre portion of the town. It is built of freestone from the "Wallace" quarry in New Brunswick. The interior is cruciform, with piers carrying arches supporting the central dome, and is very spacious, lofty and light. The finishings and fittings are in oak, with old brass railings. The floors are marble mosaic in ornamental patterns. The general contractor was Mr. Reid, of Windsor, N.S., and the contractors for fittings were The Rhodes Curry Co., of Amherst, N.S., who all did their work very well. Mr. Andrew T. Taylor, F.R.I.B.A., of Montreal, was the architect, and Mr. Hopson, of Sydney, superintended the construction.

MEDITATIONS IN A CHURCH

A good old church always sets the eye to work measuring possibilities of application to modern conditions. The church I have been seeing for the last month is not at first sight at all suggestive of conditions in Canada. It is in the middle of a little nest of halls, two half timbered and one of Queen Anne brick; which all, beautiful in the first place, are made doubly so by being reflected in a series of fish ponds round which they are grouped. These buildings were the successive residences of the head of the family which built the church. They did not do it all at once, as is evident not only from the appearance of the stone but from the structure of the church. The portion marked off by corner buttresses was built first; it most likely had a small chancel proceeding from the east side, of less width than the body, but it had neither the present chancel nor the present tower which are both built of a redder stone than that of the body and are obviously additions to it. This evidence of piecemeal work may be encouraging for church builders who build for posterity; but, in addition to the fact that we are posterity and build for ourselves, it is not so very encouraging in view of the fact that, as completed, the ratio of seating accommodation to cost is such that it would cost a congregation somewhere between 800 and 1000 dollars a head to reproduce it in Canada. Nevertheless there is no repressing the suggestiveness of the plan—a single rectangle. It is both more spacious, more handsome, and more economical than any other form, when it is properly treated and of an area within reasonable limits, and both scale and treatment are so right at Gawsworth that, after admiring it on many occasions, I have thought it desirable to get it down on paper and here is the result:

The old body 40'.0" x 29'.0" continues to be the body of the church. The chancel, though of the same width, and nearly as long, 33'.8", was built only for honour and glory, partly of God and partly of the family of the Fyttons. Here, nearer heaven by one step than the common people, they used to sit, and here are their tombs, with an inscription on one which proclaims them "Fit on's to wear a heavenly diadem." The Fytton sare gone now. The last trace of them disappeared in marriage with Lord Mohun and it was for her inheritance, this very Gawsworth, that Lord Mohun fought with Duke Hamilton, as recorded by Thackeray in Esmond. Their tombs and their sixteen quarterings in painted marble remain, and make one wish that this kind of feature (fig. 2) could be repeated in Canada. Nothing seems to sanctify a church so much as these relics of vanity; at least when there are recumbent figures upon them, (good recumbent figures,) to make one feel the presence of the dead among the living. And when, as in this case, the monuments remain in all their dignity while the family is gone forever, it becomes a case of sermons in stones, of building better than the builders knew; for the monuments which were ordained to perpetuate family honour point also to its evanescence. There is evidently something to be said for monuments, but most, I think, for life sized figures; recumbent figures, I should say; in marble; in painted marble.

The great thing, however, is to get the church built.

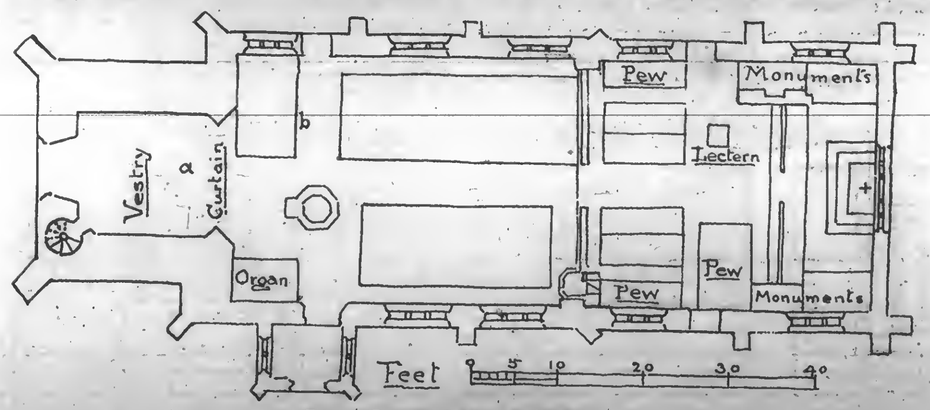

FIG. 1.—PLAN OF GAWSWORTH CHURCH.

FIG. 2.—MONUMENTS TO FYTTONS.

The plan in fig. 3 is a study of its possibility. As far as the general proportion goes, an internal view of the existing church is most satisfactory from the extreme west, i.e., standing at the entrance under the tower, where, through a high arched entrance to the tower, the whole length of the roof is to be seen. A suggestion of the view is given in fig. 4 from a photo taken from the point marked A, under the tower. The camera is not as inclusive as the eye and it was not possible to get in either the same extent of roof that is seen by the eye or, what is the great beauty of the view, the windows along the sides. The photograph was taken to serve as a sort of sectional view, showing the relation between the span and the height of the wall. This is exactly satisfactory in proportion to the length from west to east, and these dimensions—92'.0" length, 29'.0" width, and 23'.0" wall height—would make a well proportioned single chamber church as laid down in fig. 3—which is like some aisled churches with the aisles omitted.

The side passages 2'2." and the centre 5'.0" are quite enough; the seats seem to want a few inches in length to make them take six persons of moderate size with ease. An exact width would be 30'.3" and the other dimensions may be safely increased in proportion.

For hearing, the total length is not too great for the familiar words spoken from the altar, where the speaker has also the advantage of having a wall close behind him. The greatest distance for ease in speaking from the pulpit would be, as far as one can judge by the eye in the church, the distance from the east wall to b. on the passage from the north side door. This distance may then be transferred to the new plan as the distance of the chancel screen from the west end. The length thus left for the chancel is about right and the width, allowing for return passages for communicants, is no more than is necessary for good arrangement on the pulpit side, for the reading desk should range with the men rather than with the boys. The lectern may repeat the pulpit on the other side and there will thus be a mask to both hind seats and a similar motive in plan at the ends of the screen.

The three seat arrangement of the choir requires some defence as it may lead to mixing up men and boys if the balance is to be kept. But, in the first

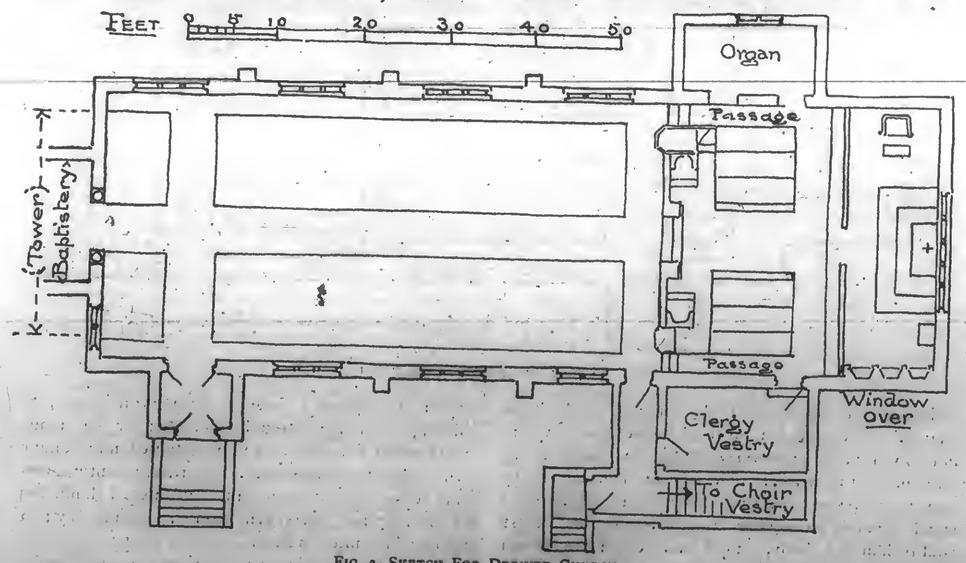

FIG. 3. SKETCH FOR DERIVED CHURCH.

place, alto boys are usually too tall for the boys' row and had better sit with the men; and secondly, the back seats are not likely to be filled except on festivals. The two front seats on each side, which would mean 10 men and 14 boys, would be enough for ordinary use.

The three seat arrangement is otherwise an advantage in reducing the depth of the chancel. It will permit the allowance of due spaciousness at the east end.

There ought to be no suspicion of narrowness in front of the communion rail or within it, and abundant room must be left for this.

The depth thus given to the choir is one bay of the roof; and the walls of the organ chamber and vestry take the place of buttresses. To make the vestry gable not wider than a bay, the church can be entered under a long slope masked by a gabled porch.

Here then is a church seating 250 and, if one can rust study from a model different enough to make some guessing necessary, both convenient and economical; that is to say, as far as the latter point is concerned, the walling is simple and dignity may depend merely on roof and windows. Apart from proportion in the latter, which costs nothing, deep reveals seem necessary; and these are the natural result of the hollow walls which are the churchwarden's friend and the coal dealer's enemy. As for the roof, it is not impossible to give a roof architectural character without great cost, but we are not so confident as formerly that this can be done merely by displaying its architectural essence. The real truth is that an acceptable open timber roof is acceptable only from its superfluity. The

FIG. 4.—VIEW LOOKING EAST.

gothic revivalists who displayed scientific trussing have left roofs that are anything but acceptable. The safest bottom idea to have is continuity of surface. Vaulted roofs and such perpendicular roofs as that of Grawsworth are one in this respect, and indeed an open roof with trusses four times as many as is necessary or four times as heavy as is necessary is not far removed from the same feeling. If pitched rather than flat, crossed by heavy construction members and recessed or double recessed, its continuity is still the leading idea if the nature of the transverse supports is not entirely revealed and the attention directed to them. I would then try this as a way—a way for which wood and plaster would suffice—to accomplish for this church a roof that would be both dignified and economical.

W. A. LANGTON.

A GRAPHICAL SOLUTION OF THE FINK ROOF TRUSS.

By Prof. C. H. Wright, of the School of Practical Science, Toronto.

Let the annexed daigram Fig 1, represent a Fink roof truss supporting the loads AB, BC, CD, DE, etc., and let the reaction of the left wall be MA. Consider first the forces acting on the point ABLM. There are two

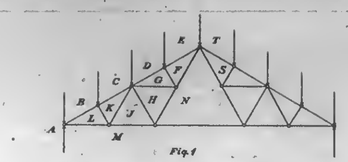

Fig. 1

known forces MA and AB and two unknown, BL and ML, exerted by the members BL & ML on the point as in Fig. 2.

From any point M, Fig. 3, draw the lines MA and AB to represent the wall reaction MA and the load AB.

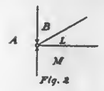

Fig. 2

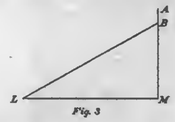

Fig. 3

Fig. 4

Through B and M draw the lines BL and ML parallel to the directions of the forces BL and ML.

Let these lines intersect in L. Then MABLM is the vector diagram for the point, and the lengths of BL and LM represent the magnitudes of the forces BL and LM acting on the point—the force BL being a push and LM a pull, hence the member BL is in compression and LM in tension.

Proceeding to the point BCKL the known forces acting are LB and BC, and the unknown CK and KL as in Fig. 4.

From any point L Fig. 5, draw the line LB parallel to the force LB and from it cut off the length LB to re-

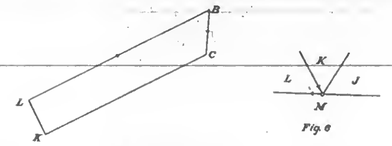

Fig. 5 Fig. 6

present the magnitude of the force and from B draw BC to represent the force BC.

Through C draw CK parallel to the force CK and through L draw LK parallel to the force LK intersecting CK in the point K.

Then LBCKL is the vector diagram for the point and CKand KL represent the forces CK and KL. These are both pushes on the point, and therefore the members CK and KL are both in compression.

Considering the forces acting on the point JKLM there are two known forces ML and LK and two unknown KJ and JM as in Fig. 6.

The vector diagram being MLKJM fig. 7, where KJ and JM represent the forces KJ and JM. As they are both pulls on the point the members KJ-JM are in tension.

Now examine the conditions existing at the point DEFG. There is one known force DE and three unknown, viz.— EF, FG and GD as indicated in fig. 8.

Two of these forces DG and EF act in the same direction and will have a resultant acting in this same direction. For these two forces substitute their

Fig. 7

Fig. 8

Fig. 9

resultant and the forces acting on the point are DE, GF and the resultant of DG and EF or R, fig. 9.

Draw the vector diagram (fig. 10) for these three forces and the lines DE, GF and R will represent the force DE, GF and R, and as GF is a push on the point the member GF is in compression.

At the point FGHN there are four forces acting, one of

Fig. 11

Fig. 10

Fig. 12

Fig. 13

which FG is known and the other FN, HN and HG are unknown and act as in fig. 11.

Of the unknown forces FN and NH act in the same direction and will have a resultant acting in that direction. Substituting this resultant for the two forces

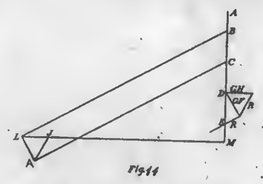

Fig. 14

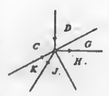

Fig. 15

and the set of forces becomes GF, GH and R2 (Resultant of FN and NH) fig. 12.

Draw the vector diagram GF, and GH and R2, fig. 13,

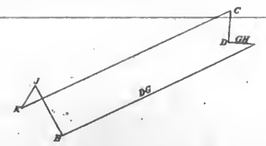

Fig. 16

and the length of the line GH gives the magnitude of the tension in the member GH.

Combine these four vector diagrams in one (fig 14

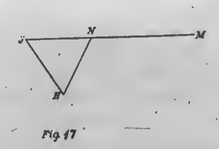

Fig. 17

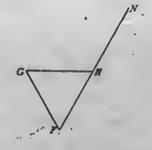

Fig. 18

The annexed diagram Fig. 15 represents the condition existing at the point CDGHJK. There are two unknown forces DG and HJ. Draw the vector diagram

J, K, C, D, GH, DG, H, J, fig. 16, and the length of DG and HJ will give the magnitude of the unknown forces.

The vector diagrams for the points MJHN, NHGFV,

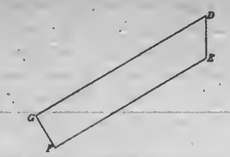

Fig. 19

and DEFG are given in figs. 17, 18 and 19 respectively.

Adding these four vector diagrams completes the combined diagram as in fig. 20.

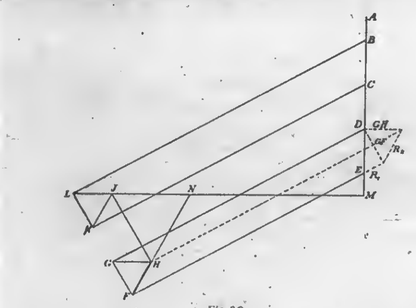

Fig. 20

Suppose the loads AB, BC, CD, DE and ET are unequal, that their total is equal to the load on the

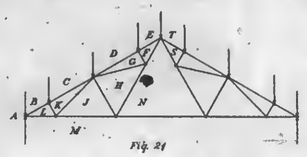

Fig. 21

right hand principal and that the lengths of the members BL, CK, DG, and EF are unequal as in fig. 21.

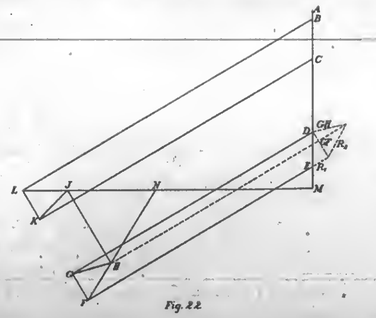

Fig. 22

Proceed as in the above problem and construct the vector diagram fig. 22.

The work of excavating the Roman remains at Silchester, in Hampshire, (England), has been productive of valuable results. A number of tesselated floors have been unearthed, while a magnificent section of mosaic pavement, with a figure representing a dolphin, in a remarkable state of preservation, and over 1,000 pots and vessels, of varying sizes and shapes, have been brought to light.

SOME COMMENTS ON THE BALTIMORE FIRE.

By a Visitor to the Scene.

Huge heaps of debris, entire streets of them, and amidst this desolate vista of broken brick or stone an occasional steel-frame structure, standing sentinel-like, over the scene of the disaster. Such is the scene left by Baltimore's recent fire and giving to Engineer and Architect the injunction. "look here upon this picture and on this." The brick rubbish is all that remains of the acres of non-fireproof buildings.

One good service was done by the wholesale conflagration in supplying owners and designers with the strongest sort of proof that modern fire-resisting practice was based on true theory. The fire-proofed building, about which many professed scepticism, has fully vindicated itself.

The Fidelity & Bond Building, Baltimore.

The intensity of the heat at Baltimore is indicated by the thoroughness with which everything combustible was licked up—hardwood flooring, door and window trim, and interior fittings. While this was the case, the efforts to protect the structural steel framing are seen to have been mainly successful, and most of the steel work is as good as ever and the walls only need superficial repairs.

The buildings with concrete fire-proofing, without exception, have passed through the fiery ordeal showing a wondertul state of preservation, under the most severe conditions.

A striking case is that of the Commercial & Farmers' National Bank, where the upper floors of the building were of mill construction and the floor over the bank was the only one fireproofed. It was a concrete floor and all the debris of falling walls, safes, etc., landed on it, but according to "Iron Age" it was absolute-

ly uninjured, while all above, including the roof, was completely ruined. Another building, the National Bank of Commerce, had all the wood-work burned out of it, but the concrete floors are absolutely intact. The writer saw a large safe being moved across the concrete floor. The banking house of Alex. Brown & Sons is another example, with floors and roof included, of expanded metal and concrete fireproofing. The military cordon and debris strewn street alone prevented this institution from opening for business the morning after the fire.

A most remarkable example of the fireproofing qualities of concrete is exhibited in a four storey structure now known as the "Concrete Building", the concrete is intact and as good as when first installed. The buildings on all sides of it were levelled to the ground and the brick walls of the building itself crumbled and fell away. The cast iron front failed also, and to-day this concrete monument stands, a paradox of a building largely consisting of floors without walls.

The concrete work at Baltimore displays an unbroken record of complete immunity from damage by the general conflagration, and without exception will not cost a dollar for repairs.

THE CHICAGO THEATRE FIRE.

On this subject Mr. Chas. Baillairge, Architect, of Quebec, writes:—"I see by the report of the Commis-

Annual Banquet of the Toronto Builders' Exchange, February 23rd, 1904.

which prior to the fire was the office of the U.S. Fidelity & Bond Co. We publish a view of this building showing its unique appearance. It is built of steel-reinforced concrete floors, roof, beams, and columns. In erecting the building, party walls belonging to adjoining buildings were used instead of building new walls, and in order to carry the floors pilasters of concrete re-inforced with steel rods were built up against the walls, and on these were carried the beams, also of concrete and steel rods. The beams are about 22 feet long, spaced about 10 feet apart. The floor slab is of reinforced cinder concrete, about 5" thick. There is no structural steel in the building, so that there can be no warping of heavy metal framework. Although the brick walls and iron front succumbed, as well as everything combustible,

sioners appointed to inquire into the cause of the disaster, that is, as to the rapidity with which the fire from the stage reached the auditorium and was the cause of the loss of so many lives in the short space of a few minutes, that while in the roof or ceiling of the auditorium there was an open ventilator, a skylight which on the roof over the stage end of the building should have been open, was on the contrary hermetically closed.

"Now, say the Commissioners, all the smoke and heated gases, which, had this skylight been open, would have passed out direct through opening, had to seek issue by the ventilator over the auditorium, thus creating a current of air which prevented the lowering of the incombustible curtain which, with the wall separating the auditorium from the stage, was intended to

cut off all communication between the two in case of fire.

This current of smoke and heated gases, which, had the stage ventilator been open, would have passed out directly through that issue, being prevented from so doing, rushed through the proscenium arch or opening with such rapidity and force that it pressed the curtain so tightly against the groove or sides in which the curtain was intended to work, that it could not be got down lower than within 14 ft. of the stage floor.

Thus the fumes and gases asphyxiated the audience and in a very few minutes; those in the galleries or upper tiers being, of course, the first victims of the disaster.

The Commissioners insist forcibly and are right in doing so, that the stage sky-light or ventilator should have been open during the performance, and that had it been opened and the gases enabled to escape in that direction, there would have been no such a current of air towards the auditorium as to prevent the lowering of the fire-proof curtain, and probably no loss of life at all on the auditorium side of the cut-fire wall between the auditorium and the stage end portions of the building, would have occurred.

This should be noted and immediately acted on by the managers of our Quebec so called Auditorium, though it is only the audience side of the structure that can be properly so called.

A ventilator over the stage can easily be made of proper dimensions and at trifling expense, which while allowing the fumes and heated gases to pass out, would exclude rain and snow, etc.

True, there are the so called emergency doors—five of

Mr. R. G. Kirby,
President Toronto Builders' Exchange.

them on the eastern and four on the western side of the building, with iron staircases leading from them to ground level; but in such a climate as this, the landings of these outer stair-ways might, in the case of a heavy fall of snow, become impeded during a single sitting or representation and the outward opening of the emergency doors be thus prevented.

There should be a lad at each door with strict orders not to leave his post during the performance; for at the Paris Charity Bazaar fire, there were seven emergency doors, but no one having been stationed at them to open them, when the explosion of the acetylene apparatus of the cinematograph occurred, the audience from the far ends of the bazaar building (300 ft. in length) had to travel 150 ft. to reach the central door by which they had entered, not being aware of the existence of the emergency doors.

Had these doors been opened in time all would have escaped, with scorched heads and shoulders, no doubt from the falling draperies but with their lives at any rate, and three months would have repaired all such sores and singings as were caused by the burning hangings falling from above.

Mr. Geo. C. Young,
1st Vice-President London Builders' Exchange.

The only really safe theatre of more than one story in height, as at the Somuer Park, Montreal, which is open all around and allows of immediate escape on all sides, may be said to be at Antwerp, Bruxelle, erected according to the system proposed by the undersigned in 1884 and exhibited in Paris in 1900. In this theatre there are five tiers of inside galleries one over the other, with corresponding iron balconies surrounding the auditorium end of the building on the outside. To each tier of superposed boxes or galleries there are 25 doors—125 in all—opening onto the outer balconies, with iron staircases descending from the one to the other to ground level. But even with all these precautions, the stage ventilator recommended by the Chicago Commissioners and the keeping of it open during each performance, would be none too much of a safe-guard against the possibility of the stage fireproof curtain being out of order.

When the undersigned built the Quebec Academy of Music in 1854, he had designed to have an iron cut-fire curtain (asbestos being then unknown) and the iron covered on the auditorium side with mirror in vertical strips of some 3 ft. in width, with silver-edged bars between them to keep the glass in position; but funds were lacking to carry out the scheme, and though the mirror was imported for the purpose, the rigid iron curtain was never made.

Chas. Baillairge, Architect.

Quebec, March 18, 1904.

PUBLICATIONS.

One of the latest additions to the rapidly growing literature on the use of cement for constructional purposes is a book of 200 pages, entitled "The Architects' and Engineers' Hand Book of Re-Inforced Concrete Constructions," by L. J. Mensch, C.E., published by Wm. Seavert, Chicago, price $2.00. It treats of the use of concrete for a great variety of purposes, giving results of tests and illustrations showing important works which have been carried out in this material.

PHOTOGRAPHY FOR ARCHITECTS.*

By Francis R. Taylor.

Photography should not be considered as antagonistic to sketching. It has a utility in the education of the architect by producing an accurate delineation of old buildings unattainable by a sketch. It must not be forgotten that however valuable a sketch or measured drawing may be to the individual student who prepared it, there is the personal error to bear in mind when this method of delineation is applied for general study.

Photographs in conjunction with measured drawings undoubtedly form the best means for architectural study and research. It may be mentioned that in the Architectural Association Sketch-Book there are examples of measured drawings together with a photograph of the work. This method of illustration might be employed with advantage to a much larger extent. Whenever any old building of interest is to be pulled down to make way for modern improvements, or for other reasons, a set of measured drawings with a series of photographs form the best record of the old work.

Another use of photography as a means of illustration occurs in classes of instruction for architects when lantern slides are available ; these enable all present to see, whereas diagrams and plates on the walls are only visible from certain parts of the room.

Lantern slides for architectural lectures should be made with a view to suitability of purpose. Photographs of buildings, both externally and internally, would be useful to illustrate the grouping and general effect, and then should follow photographs of towers and spires, of piers and arches, of caps and bases, of doors and windows, of vaulting, etc., to illustrate the treatment of the parts, and, lastly, of mouldings and ornament.

In illustrating constructive subjects the same principles should be adhered to—explanatory lantern slides to illustrate the manufacture and uses of the various materials, and then slides showing the different methods of construction.

The use of telephotography in the study of architecture is one which should receive careful consideration. In many instances parts of a building well worth studying are inaccessible for measuring ; in these cases an ordinary photograph gives a general idea of the composition and a telephotograph the details.

REPRODUCTION OF DRAWINGS.

The utility of photography in the practice of architecture might receive far more attention than it does. In many instances the only use to which photography is put in architectural practice is in the reproduction of drawings by the ferro-gallic process. In this process the reproduced drawings are either on a thin paper or a paper similar to Whatman's, and a black or brown line is obtained on a white ground. The advantage of the process is that the reproduced copies can be colored similarly to an original drawing. A great saving of time is effected, because from one complete set of tracings any number of reproductions can be obtained. If the reproductions are to be kept for a considerable time as in the case of copies for the authorities, care must be taken in the selection of the paper owing to its tendency to fall to pieces after a time. For this reason the authorities will only accept photographic reproductions on linen. The makers of the paper might consider the best means of surmounting this difficulty. It may be mentioned here that some of the papers shrink slightly in the process of obtaining the reproduction ; this emphasizes the necessity for fully dimensioning all drawings.

The ferro-prussiate process with a white line on a blue ground is sometimes used, but as colouring is then out of the question it is not so suitable for general architectural work. Its use is limited to drawings where colouring is not essential, as, for instance, in details of steel construction.

Besides this special application, the use of photography in architectural practice is generally limited to what may be termed the legal phase of our profession, although a wider application would be a distinct gain. No one will deny that photographs of buildings about to be pulled down are valuable records, and in ancient light, easement, party structure and such like cases would always be useful on one side or the other.

If the building happens to be one of considerable architectural interest, then the value of the record cannot be overrated.

Photographs of a building at its various stages of erection, with the dates and in some instances the time noted thereon, would be a valuable record of this class of work, and, in addition, would be very serviceable in the valuation of certificates. Engineers often adopt this method, with the best results, and there is no reason why architects should not do so.

Photographs of the finished building should in all cases be obtained, and a comparison made by showing the photograph side by side with the perspective drawing. Photographs should be taken by oneself.

It is impossible for a professional photographer to know exactly what is wanted unless he happens to have made a thorough study of architecture, and we know that in the majority of cases he has simply a mere smattering of the requirements.

It might, of course, be urged that the professional photographer could do the work under our guidance, but it will be found that this method is expensive, and is, in reality, only applicable in those instances where selection of subject is not required to any great extent.
